The knowledge package
[v1.20 — 2019/12/03]

Thomas Colcombet
thomas.colcombet@irif.fr

December 3, 2019

Abstract

The knowledge package offers automatic tools and commands for helping the writer of a (scientific) document to have all notions (hyper)linked to places where these are defined. Using the standard tools of \LaTeX{} for doing that would be extremely tedious. Eventually, it is intended to use the package for producing scientific semantic aware documents.

1 History

2016-06-07 \knowledgemacro is now renamed to \knowledgedirective.

2017-01-13 \AP has been recoded, and is now more properly aligned in the margin. The visible anchor points option has also been made usable without the xcolor package.

2017-01-13 The package scope option can now be omitted. This in particular avoid clashes with the over-restriction on the structure of the document it entails. It should be improved to stop overloading the \begin command.

2017-01-13 The overloading of \begin and \end was done as protected commands, which should not be the case to be consistent with the behaviour of LaTeX (for instance, this was giving an extra line in the title in the conference mode of the class IEEEtran). Corrected: these commands are not protected anymore.

2017-01-15 A workaround for an incompatibility between the hyperref and the twocolumn mode as been added in the macro \knowledgefixhyperreftwocolumn (thanks to Daniela Petrisan).

2017-01-15 Added the \directivesynonym.

2017-01-15 Added the noknowledge package for minimizing the effects of not having knowledge activated.

2017-01-17 Changed the way options are handled, decoupling the package options (options of \usepackage) from the configuration options (see \knowledgeconfigure).

2017-01-17 Proper treatment of ‘final’ option and composition options.

2017-01-17 Added the option \fixhyperreftwocolumn as a shorthand for calling \knowledgefixhyperreftwocolumn (thanks to Daniela Petrisan and Luca Reggio).

2017-01-18 Added the configuration option \notion that offers a basic configuration compatible with xcolor or not, and final and composition modes.

2017-01-19 Added \phantomintro and an explanation on how to deal with align*.

2017-02-20 Removed the warnings of latex for unknown labels in autoref.

2017-02-20 Removed nasty error making \AP not operative when anchor points were not visible.

2017-02-21 Added the \protectlink directive.

2017-02-21 Added the \hyperlinks configuration.

2017-02-27 visible anchor points is active by default now.

2017-02-27 A simple example is now included.

2017-02-28 Minor changes on the documentation.

2017-02-28 Added the \scope environment.

2017-02-28 Added the \protectlink and \unprotectlink configuration directives.

2017-02-28 Added the \knowledgeconfigureenvironment command.

2017-03-03 Added the \breaklinks faq (thanks to Luca Reggio for the request).

2017-03-10 Added the “...” and “...@...” notations and the quotation mode (requested by Gabriele Puppis and Andreas Krebs).

2017-03-11 Added the “...@...” and “...@...” notations.

2017-03-13 Corrected for being compatible with version of expl3 posterior to Mars 2015 (\c_sys_jobname_str does not exist anymore). (Thanks to Jean-Éric Pin).

2017-03-14 Corrected that the @ letter was left a letter after \knowledgefixhyperreftwocolumn.

2017-04-09 Internal change of code, for scope handling and for the quotation notation: slowly going toward an extended quotation notation that can make the scope of search explicit.
2017-04-09 Added the \protect quotation configure option, that is given a list of environments, and deactivates automatically the quotation notation when in there environments. This is a simple code for the moment. Typically, one can use \knowledgeconfigure{protect quotation=tikzcd}. For the moment, it is not explained in the document.

2017-04-19 Changed the display code such that nested knowledges behave properly: before, the introduction would be performed for the object and the subobjects.

2017-04-20 The electronic mode has been added, and the ‘final mode’ is now renamed into paper mode. The \knowledgepackagemode configuration variable is also available for easier scripting.

2017-06-06 FAQ on deactivating the quote in Emacs (thanks to Sylvain Perifel).

2017-06-08 Removed the noknowledge package and all references to it.

2017-06-08 Removed the knowledgeutils.sty and scopearticle.sty which are now integrated in the main file.

2017-06-08 The file knowledge-example.tex has been improved.

2017-06-09 First release of version 1.0 on CTAN.

2017-06-10 Corrected the quotation notation to make it expandable for avoiding problems in table of contents (the @ was not working).

2017-06-11 Corrected a bug linked to changes of expl3 on recent distributions (pointed by Murray Eisenberg). Release of v1.01 on CTAN.

2017-06-27 Overloaded labels now perform an expansion of the argument (this was causing problems with biblatex).

2017-06-28 Options log-declarations of xparse package removed (causing clash with other packages, as pointed by Juliusz Chroboczek). Release of v1.02 on CTAN.

2017-06-30 added the field labelizable_bool to areas. Coded missing features of scoping. Now the scope= directive works with as parameter an enclosing area, or a label.

2017-06-30 Added in the source a Regression subdirectory containing files to be tested (so far only one: regression-scope.tex)

2017-07-01 Corrected a conflict between the scope and makeidx option.

2017-07-03 Scoping becomes operational.

2017-07-04 The documentation for notion and intro notion are added (thanks to Fabian Reiter).

2017-07-09 Added boolean environment_bool field to areas, in order to resolve an incompatibility with the package standalone noticed by Fabian Reiter.

2017-07-20 Scoping becomes fully operational, with the parenthesis notation of \kl and \intro. The use of scope has been recoded. Now scope links reuse implicitly the key as a link. Documentation updated.

2017-07-26 File and line numbers added in the kaux file. Added the option diagnose line= to deactivate it.

2017-07-26 Corrections to the documentation. Version 1.03 on CTAN.

2017-07-28 Corrected a bug of scoping in the context of synonyms. Added ctan for producing the ctan zip file.

2017-08-06 Now passes the compliance test check-declarations of expl3 (thanks to Marc Zeitoun)

2017-09-12 The hidelinks option of hyperref is now always activated.

2017-09-25 Ancient version of xparse does not have \NewExpandableDocumentCommand. Corrected. Version 1.05 on CTAN.

2017-10-10 Bug in the implementation of \knowledgegenewvariant (that was invisible for
older versions of \texttt{expl3}). Found and corrected (thanks to Marc Zeitoun). Version 1.06 on CTAN.

2017-10-15 Diagnose extended (suggested by Fabian Reiter). Minor corrections. Version 1.07 on CTAN.

2017-10-17 Added \texttt{cyclic color} and \texttt{cyclic colors=}. Reorganization of the structure of the code for producing a better CTAN archive. Version 1.08 on CTAN.

2018-01-31 Added the \texttt{strict} configuration option.

2018-02-05 Added the \texttt{smallicaps} formatting directive.

2018-02-17 Corrected incompatibility with latest version of \texttt{expl3}. Version 1.10 on CTAN.

2018-02-21 Bug correction concerning the activation of scopes.

2018-02-21 Documentation improvement for \texttt{Emacs} (thanks to Michaël Cadilhac).

2018-02-24 Documentation improvement for the environment \texttt{thebibliography}.

2018-05-17 Correction to be compatible with the latest version of \texttt{expl3} (thanks to Leo Stefanesco).

2018-07-26 Compatibility with utf8 symbols in labels (thanks to Yves Guiraud).

2018-11-22 Corrected bug for \texttt{makeidx} (thanks to Sylvain Schmitz). V1.14 on CTAN.

2019-01-27 Minor improvement of the doc, and hiding links in it. V1.15.

2019-02-15 Correction of a placement problem with \texttt{\AP}. V1.16.

2019-05-23 Adding of the \texttt{\^c-notation} for the \texttt{\knowledge} command. Explicit scopes are introduced. Updating of the documentation. \texttt{up} directive in math mode now silently does nothing, and \texttt{\knowledgerective} now forbids redefinitions by default (thanks to Léo Stefanesco).

2019-07-02 Removing the ‘\texttt{kl}’ and ‘\texttt{intro}’ styles that prevented a proper configuration of \texttt{intro notion} (thanks to Léo Stefanesco).

2019-10-03 Update of the documentation, and V1.17.

2019-10-27 Bug correction and added the \texttt{patch label} configuration directive (thanks to Rebecca Turner). V1.18.

2019-11-19 Now the labels are evaluated before being written to the \texttt{kaux file} in a \texttt{\KAuxNewLinkScopetagInstance} command (bug fix). V1.19.

2019-11-29 Help added in the \texttt{diagnose file}. \texttt{bar suggestion} (still working) renamed to \texttt{diagnose bar}, and activated by default. \texttt{patch label} is renamed into \texttt{label scope}.

2019-12-02 The \texttt{kaux file} is now checked for completeness before being used. This should avoid errors when the previous compilation failed.

2019-12-03 Corrected bug in the scope access. V1.20.
2 Quick start

The knowledge package offers several capabilities for handling colors, changing the display style, defining internal and external hyperlinks, producing an index, etc... All these possibilities arise from defining explicitly or implicitly knowledges associated to terms in plain english (or other languages).

We start by describing a certain number of problems/scenarios that a user may be confronted to, and show how to solve them. In the subsequent sections, a more detailed account of how the package works and can be parameterized is given.

There is also a file knowledge-example.tex that can be used as a starting point.

2.1 Linking to outer documents/urls, and to labels

The problem

I have a lot of external url’s that I would like to [very] often have a link to, but I do not want to always type the full url. I do not want to remember weird labels/internal references/macro names either.

A solution is as follows. One first loads the knowledge package with option hyperref using either:
\usepackage[hyperref,quotation]{knowledge}

or even better:
\usepackage[hidelinks]{hyperref}
\usepackage[quotation]{knowledge}

\[If you want to use the "···" notation.\]

Then, in the preamble (or in an external file), one uses commands of the form:
\knowledge{latex}{url={https://en.wikipedia.org/wiki/LaTeX}}

This configures the text 'latex' to be associated with the sole directive url=, which means an hyperreference to this address.

Finally in the body of the paper, the sole extra command \kl (or the "-symbol if the quotation option is activated) is used, with as parameter a text. This text is searched for, and the directives attached to it (here url=), are used for formatting its printing\(^1\). Hence:

This package has been written for use in \kl{latex}.

or, if the quotation option is activated,

This package has been written for use in "latex".

\(^1\)This resembles a lot a macro so far. It nevertheless differs in that: (a) if not defined, it does not make the compilation fail as a macro would, and thus does not interfere with the writing process, (b) any text can be used and not only alphabetic letters as in \TeX, (c) you do not have to care about the space after, and (d) in fact the machinery for resolving the meaning of a knowledge is much more powerful than simple macro execution.

\[Hint.\] You may use other options like xcolor for allowing debugging with colors (for undefined knowledges).

\[Hint.\] If the knowledge is not defined, this does not make the compilation fail. In fact, it is good practice to use many \kl commands or "···" notations while writing a text, and only resolve these questions at the end (see also the diagnose file).
This package has been written for use in LaTeX.

Variation. But in fact, I would like \texttt{latex} to also be properly typeset \LaTeX, and in gray. This requires to load the package with the \texttt{xcolor} option (for being able to use colors, obviously), or by loading the package \texttt{xcolor} before, and then modify the \texttt{knowledge} command using extra directives:

\begin{verbatim}
\knowledge{latex}{url=https://en.wikipedia.org/wiki/LaTeX, text=\LaTeX, color=gray}
\end{verbatim}

yields with the same text

This package has been written for use in \LaTeX.

The directives \texttt{text=} and \texttt{color=} have quite obvious meaning. Directives can also control the style using \texttt{emphasize}, \texttt{boldface}, \texttt{italic}, \texttt{typewriter} and so on. See Section 5.3 for a complete list of directives.

Variation (synonyms). It happens very often that there are several ways to name a notion, because of capitalized letters, conjugacy, grammar, or simply because it is not explicitly named in the text. There are two ways to resolve this issue. The first is to use the syntax

\begin{verbatim}
%kl[knowledge]{text}
\end{verbatim}

or

\begin{verbatim}
"text@knowledge"
\end{verbatim}

the result is that the text \texttt{`text'} is displayed, but urls, colors, etc from `knowledge' are used.

Another more systematic way to do it is to declare synonyms. This can be achieved using a `'|'` separated list of texts in the \texttt{optional parameter} of the \texttt{knowledge} command, it is possible to add a list of `synonyms', such as in:

\begin{verbatim}
\knowledge{latex}[LaTeX|Latex|LATEX]
\end{verbatim}

This is interesting for people's name that can be displayed in various ways depending on the context. Hence

\begin{verbatim}
\knowledge{Donald Ervin Knuth}[Donald Knuth|Knuth]
\end{verbatim}

would allow

\begin{verbatim}
\kl{Knuth} as well as \kl{Donald Knuth}.
\end{verbatim}

or simply "Knuth" as well as "Donald Knuth" and so on to all point to the same web address. It is even more convenient to use it for nouns that are sometimes in plural form or at the beginning of a sentence. Hence:

\begin{verbatim}
\knowledge{group}[groups|Groups|group morphism|group morphisms|Group morphisms]
\end{verbatim}

\begin{verbatim}
{url=https://en.wikipedia.org/wiki/Group_(mathematics)}
\end{verbatim}
or the more readable and maintainable:

```latex
\texttt{\usepackage[url=https://en.wikipedia.org/wiki/Group_(mathematics)}
| group
| groups
| Groups
| group morphism
| group morphisms
| Group morphisms
```

makes it possible to use the notions in many contexts:

"Groups" form a category when equipped with "group morphisms".

### 2.2 Linking inside a document

**The problem** I am writing a long scientific document with many notions tied together (typically, I have made all my best for clarifying but nevertheless it remains obscure, or it is a long survey involving many subfields, or a book, or a PhD thesis\(^2\)). I would like all the notions to be linked inside the document for being able in one click, whenever something is used, to jump to its definition. I also want to easily write an index. However, I do not want it to be a hassle when writing.

A solution is as follows. First load the \texttt{knowledge} package in the preamble:

```latex
\usepackage[xcolor,hyperref,notion,quotation]{knowledge}
```

with suitable options: \texttt{hyperref} for links, \texttt{xcolor} for colors (if required, but always advised), \texttt{quotation} for using the quotation notation and \texttt{notion} for automatic configuration of the \texttt{notion} directive.

Then write the document using \texttt{\smallint}ro (or """" if \texttt{quotation} is activated) when a notion is defined/introduced, and \texttt{\smallk}l (or """" if \texttt{quotation} is activated) when it is used. For instance:

```latex
\AP A \smallintro{semigroup} is an ordered pair \$(S, \cdot)\$ where \$\cdot\$ is an associative binary operator over \$S\$. 
\[...
\AP A \smallk{monoid} \$(M, \cdot, 1)\$ is a \smallk{semigroup} \$(M, \cdot)\$ together with a neutral element \$1\$.
```

or when the quotation notation is activated:

```latex
\AP A ""semigroup"" is an ordered pair \$(S, \cdot)\$ where \$\cdot\$ is an associative binary operator over \$S\$. 
\[...
\AP A ""monoid"" \$(M, \cdot, 1)\$ is a ""semigroup"" \$(M, \cdot)\$ together with a neutral element \$1\$.
```

This yields

---

\(^2\)Reviewers should appreciate...

---

Note that the \texttt{\AP} command is made visible thanks to a red corner.
A semigroup is an ordered pair \((S, \cdot)\) where \(\cdot\) is an associative binary operator over \(S\).

A monoid \((M, \cdot, 1)\) is a semigroup \((M, \cdot)\) together with a neutral element 1.

Undefined knowledges are in brown (it is an important feature that the compilation does not fail: undefined knowledges should not interfere with the writing of the document, which is the main activity of the writer). One can now see the list of such problems in the file ‘filename.diagnose’. One can in particular find in the ‘Undefined knowledges’ section:

\begin{verbatim}
knowledge{semigroup}{}
knowledge{monoid}{}
\end{verbatim}

Which means that both ‘monoid’ and ‘semigroup’ are unknown knowledges.

To solve this, let us copy these two (or more) lines in the paper\(^3\), adding the notion directive (which is a configured version of the autoref directive, meaning essentially that you want to use the features of the intro command), i.e., in the preamble:

\begin{verbatim}
knowledge{semigroup}{notion}
knowledge{monoid}{notion}
\end{verbatim}

The result is then (after two compilations):

\begin{verbatim}
A semigroup is an ordered pair \((S, \cdot)\) where \(\cdot\) is an associative binary operator over \(S\). [...] A monoid \((M, \cdot, 1)\) is a semigroup \((M, \cdot)\) together with a neutral element 1.
\end{verbatim}

Clicking on ‘semigroup’ now jumps to the place it was introduced, and very precisely at the location of the red corner depicting the presence of the \texttt{AP}-command. If now one adds the option electronic while loading the package, then the red corners disappear as well as the brownish undefined knowledges which become black. When using the option paper, the links are still there, but all texts are in black.

It is very often the case that for plain english (or other languages) some terms can be used in several forms; verbs can be conjugated; nouns can be plural, and so on. So usually the lines added to the file look more like:

\begin{verbatim}
knowledge{semigroup}{semigroups|Semigroups}{notion}
knowledge{monoid}{monoid|Monoids}{notion}
\end{verbatim}

or, using the modre readable ‘\texttt{\textbar}’-notation:\(^3\)

\(^3\)It is good practice to use a separate file, something like ‘paper-knowledge.tex’.

10
Now, using a text like
"Monoids" are simply "semigroups" in which...

will properly be linked to the definition of a semigroup and a monoid.

Finally, in particular for large documents, it is good to have an index. For this, one should load the package \texttt{makeidx} before \texttt{knowledge}. Then use it normally: putting \texttt{\makeindex} in the preamble and \texttt{\printindex} at the end of the document. The \texttt{knowledge} commands are not easily adapted:

\begin{verbatim}
\knowledge{notion,index=semigroup}
| semigroup
| semigroups
| Semigroups
\end{verbatim}

\begin{verbatim}
\knowledge{notion,index=monoid}
| monoid
| monoids
| Monoids
\end{verbatim}

See Section 3.8.3 for more details on making an index.

## 2.3 Mathematics

The examples above show various techniques for using \texttt{knowledges} for enhancing the information associated to terms. In fact, these techniques are not incompatible with mathematics. Imagine, for instance that you would like each time a macro \texttt{\monoid} is met, to display $\mathcal{M}$, you would do for instance:

\begin{verbatim}
\newrobustcmd\monoid{\mathcal M}
\end{verbatim}

Imagine that furthermore, you would like to hyperlink to the definition of a monoid. A standard \texttt{\kl} command does the job:

\begin{verbatim}
\newrobustcmd\monoid{\kl[monoid]{\mathcal M}}
\end{verbatim}

What is $\monoid$ ?

would yield:

```
What is $\mathcal{M}$ ?
```

\textbf{The problem 3} But I want more. I want to be able to introduce variables. Even better, I would like to be able to have variables hyperlinking to the place of their

\footnote{It is highly advised to not use the \texttt{quotation notation} in math mode or macros.}
introduction, knowing that the same variable name may mean different things depending on the lemma or proof we are in. Hence, I want to properly control the scope of knowledges.

To be done, this requires to use scoping. The principle of scoping is that a knowledge can be attached to a particular context. This is particularly true when typesetting mathematics: a variable is meaningful inside a statement, and inside the proof of the statement. Furthermore, the same variable name may reappear elsewhere with a different meaning.

The following code gives an idea of what is possible using scoping:

\begin{lemma}\label{theorem:main}
\knowledge{n}{notion}
For all number $\intro n$, $\ldots$
\end{lemma}

\begin{proof}[Proof of theorem \ref{theorem:main}]
\knowledgeimport{theorem:main}
Inside the proof, $\kl n$ is hyperlinked to the theorem...
\end{proof}

More on scoping can be found in Section 3.5.

The use of variants of \kl is also useful for typesetting mathematics. It allows for instance, to implicitly execute the \knowledge command at the same time of the introduction. See 3.4.3 for more detail.
3 Usage of the \texttt{knowledge} package

3.1 Options and configuration

Options are used to activate some capabilities. Some options have to be used when loading the \texttt{knowledge} package, while some others can also be used inside the document thanks to the use of \texttt{\textbackslash knowledgeconfigure}. In this section, we review these \textit{package options}.

3.1.1 Options at package loading

The options that can be used in the optional parameter of \texttt{\usepackage} when loading the \texttt{knowledge} package belong to the following classes:

\textbf{Writing mode} The \texttt{paper}, \texttt{electronic} or \texttt{composition} modes are possible (\texttt{composition} is by default) (see Section 3.1.2 for more details). These modes change several rendering settings.

\textbf{Other packages} some of the options concern the loading and the use of other packages (\texttt{hyperref}, \texttt{xcolor}, \texttt{makeidx}, ...). Note that these package can also be loaded before \texttt{knowledge}. This is explained in Section 3.1.3.

\textbf{Configuration options} as used by the command \texttt{\textbackslash knowledgeconfigure} can be used when loading the package.

\textbf{Scoping} The \texttt{scope} option makes the package aware at a fine level of the structure of the document (see Section 3.5 for explanations). This provides, for instance, the possibility to define pieces of \texttt{knowledge} that are attached to a sections of the document.

3.1.2 Writing mode

There are three \textit{writing modes} usable when loading the package \texttt{knowledge}:

- In \texttt{paper} mode, the paper is rendered as for printing: in particular, no informative colors are visible. Hyperlinks are nevertheless present.

- In \texttt{electronic} mode, the document has some colors witnessing the existence of the links for the reader to know that clicking is available.

- In \texttt{composition} mode, the document has colors helping the writing: undefined knowledges appear explicitly, anchor points are displayed, and so on.

Activating the modes is obtained either at load time using one of:

\begin{verbatim}
\usepackage[paper]{knowledge}
\end{verbatim}

or

\begin{verbatim}
\usepackage[electronic]{knowledge}
\end{verbatim}

or by setting before loading the variable \texttt{\textbackslash knowledgepackagemode} as in:

\begin{verbatim}
\def\knowledgepackagemode{paper}
\end{verbatim}
The idea is that this can be used in automatic compilation scripts. For instance, using in a terminal:

```
pdflatex \"\def\knowledgepackagemode{electronic}\input{file.tex}\"'
```

would result in compiling ‘file.tex’ using knowledge in **electronic mode**.

The following primitives are available to the user for **writing mode-sensitive configuration**:

\begin{verbatim}
\IfKnowledgePaperModeTF{true code}{false code}
\ifKnowledgePaperMode true code \[\else false code\] \fi
\IfKnowledgeElectronicModeTF{true code}{false code}
\ifKnowledgeElectronicMode true code \[\else false code\] \fi
\IfKnowledgeCompositionModeTF{true code}{false code}
\ifKnowledgeCompositionMode true code \[\else false code\] \fi
\end{verbatim}

3.1.3 Automatic loading of other packages

A certain number of **package options** coincide with the loading of other packages. For the moment, the packages that are concerned are **hyperref**, **xcolor**, and **makeidx**.

For activating these functionalities, it is sufficient, either to load the package before the knowledge package, or to name it explicitly as an option for knowledge. Loading separately the package is convenient for setting options for it. For instance, a typical preamble may look like:

\begin{verbatim}
\documentclass{article}
\usepackage[svgnames]{xcolor}
\usepackage[draft]{hyperref}
\usepackage[makeidx]{knowledge}
\end{verbatim}

Such a sequence will activate the **knowledge** package using the features related to **xcolor** configured with svgnames option, to **hyperref** configured with **draft** option, and to **makeidx** with its standard configuration.

In fact, the syntax when a package is loaded as an option of **knowledge** is of the form ‘package=choice’ in which choice can take the following values:

**active** The package will be loaded, and all the capabilities that it triggers are activated. This is the implicit meaning when nothing more is specified.

**inactive** The package is not loaded, and no capabilities are activated (even if it had been loaded previously by another \usepackage command).

**compatibility** The package is not loaded. The directives it used do not cause any error, but have no effect.

**auto** If the package was loaded before, then the associated capabilities are activated. This is the default behavior when the package is not named while loading.
Currently, the packages that can be loaded are:

**hyperref** which activates all the (auto)referencing capabilities.

**xcolor** which activates coloring commands.

**makeidx** for handling the index automatically.

### 3.1.4 Configuring and \knowledgeconfigure

Some part of the configuration can be done outside of the \usepackage command that loads the **knowledge** package. This is done using the \knowledgeconfigure command:

\knowledgeconfigure{configuration directives}

Note that by default, the configuration directives used by \knowledgeconfigure can be used in the optional parameter of \usepackage when loading the **knowledge** package, but the converse is not true. **Configuration directives** consists of a comma separated list of elements that can take the following values:

- **diagnose bar**= (de)activates the ‘|’-notation in the diagnose file. True by default.
- **diagnose help**= can be set to true or false. It activates or deactivates the help in the diagnose file. True by default.
- **diagnose line**= can be set to true or false. It activates or deactivates the line numbering in the diagnose file. False by default.
- **fix hyperref twocolumn** triggers a hack that solves a known problem that may occur when **hyperref** is used in two-columns mode.
- **label scope** enables or disables the redefined \label command, which helps automatically define scopes (default is true).
- **notion** configures the notion directive which is a refined version of **autoref**.
- **protect quotation**= is followed by a comma separated list of environments in which the quotation notation will be automatically deactivated (surrounded by braces if more than one item in the list).
- **protect link** and **unprotect link** starts and ends respectively a zone in which the **knowledge** package do not create hyperlinks. These can be nested. This is typically useful around, e.g. the table of contents.
- **quotation** activates the quotation notation, which allows to use "···", "···@···" and "···@···@···" instead of \kl commands and ""···"", ""···@"" and ""···@···"" instead of the \intro command.
- **strict** is a Boolean option which, when activated, turns some warnings (for instance when a knowledge is redefined) into errors.
visible anchor points is an option that makes visible or invisible the anchor points of the \AP and \itemAP commands. Usually, this is automatically set to true when the composition mode is used (the default), and to false when the paper mode or the electronic mode are used.

3.2 What is a knowledge?

A knowledge is often informally used in this document. Essentially, it captures what is an elementary concept in the document. Internally, a knowledge is identified by three components:

The **knowledge name** is a \TeX string that has almost no limitation (but being well balanced, and containing no ♯). It is the text entered by the user for defining and using the knowledge.

The **scope** which is a simple string identifying where the knowledge is usable. The scopes are generated by the system. For instance, internally, each section will be uniquely named ‘section-1’, ‘section-2’, and so on (this is invisible for the user). Each knowledge is primarily valid in exactly one such scope. Knowledges defined in the preamble are given the scope ‘document’. Usually, the user refers to scope using, for instance, labels.

The **namespace** is a simple string that is used for avoiding clashes. It is most of the time simply ‘default’. It is ‘style’ for styles (that are internally as knowledges). It is a possibility available to a developer to, when developing a new set of functionalities, use a different namespace for avoiding clashes of names (for instance if one wants a french and an english set of knowledges that should not conflict, and would use separate sets of macros). Usually, a normal user does not see namespaces.

3.3 The \knowledge command and variations

In this section, we describe the main commands that create knowledges. The main one is \knowledge. It can also be used in combination with \knowledgedirective, \knowledgestyle and \knowledgedefault.

3.3.1 General description of the \knowledge command

The key command for introducing knowledges is \knowledge. There are two syntaxes. The standard one is:

\begin{verbatim}
knowledge{knowledge name}[synonym 1|synonym 2|...]{directives}
\end{verbatim}

The second one is the ‘|--notation’:\footnote{This is a non-standard \TeX syntax. The rule is that each knowledge appears in a distinguished line that starts with some spaces and a ‘|’, and ends at the end of the line. Detecting the end of the line requires to change the catcode of the end of line character; this is not robust for being used in an argument or a macro.}
The \textit{knowledge name} as well as the \textit{synonyms} are plain text strings describing the knowledge. It may contain any combination of symbols, including accents or special characters as long as it well bracketed. This string will be used to fetch the knowledge. Note (and this is a standard \TeX{} behavior) that several consecutive spaces is the same as one or a line feed. In the normal syntax, \textit{synonyms} are given in a ‘|’ separated list, while in the ‘|’-notation each of them has to be in a distinct line. In the ‘|’-notation, an \textit{optional scope} can be given after each \textit{knowledge name/synonym}.

The \textit{directives} consists of ‘key=value’ statements in a comma separated list. There are many \textit{directives}. A list of them can be found in Section 5.3. New ones can be defined using the \texttt{\textbackslash knowledgedirective} command.

The principle of the \texttt{\textbackslash knowledge} command is to introduce a new \texttt{knowledge}, ready for being used. However, what it does exactly depends a lot on the situations. First, the \textit{directives} (a comma separated list of ‘key=value’ commands) are parsed, and from it, the namespace and \textit{scope} of the knowledge are determined, and it is decided if it will be defined immediately or postponed to the next compilation phase (using the \texttt{\textbackslash kaux} file).

### 3.3.2 Targeting and the corresponding directives

The \texttt{\textbackslash knowledge} has to decide what to do when defining something. The basic behaviour is as follows:

- If the \texttt{\textbackslash knowledge} command is used in the preamble, then the \texttt{knowledge} given as argument is defined immediately (the same effect can be obtained using the \texttt{\textbackslash now directive}), and is accessible in the first compilation phase everywhere in the document (one extra phase is nevertheless required if \texttt{autoref} or \texttt{ref=} directives are used, for the \texttt{hyperref} to do its job, or if \texttt{scope=} is used). This is the simplest way to use \texttt{\textbackslash knowledge}.

- Otherwise, the \texttt{knowledge} is written in an external file (the \texttt{\jobname\.kaux} file), and the \texttt{knowledge} will be really usable in the next compilation phase. This is particularly useful in conjunction with the \texttt{scope option}: the \texttt{knowledge} will have a scope depending on where it is introduced (for instance the document, or a theorem, or a lemma). The same \texttt{knowledge name} can then point to different \texttt{knowledges} depending on where it is used.

- Exporting (not implemented) furthermore writes a document containing a list of \texttt{\textbackslash knowledge} commands giving access to its content. This is to be imported by another document.

The targeting directives refine the above defined behaviour:
**scope** or ‘@’ in the ‘|’-notation When using a directive ‘**scope**=name’ or ‘@@name’ in the ‘|’-notation, the scope of the definition can be modified. `\knowledge` will first check if there is an outer area of this name (theorem, section, ...), that accepts knowledge (only **scope** environments are subject to this unless `\knowledgeconfigureenvironment` is used, or the **scope** package option is used when loading the package). If this is the case, the knowledge will be associated to the corresponding instance. For instance, inside a theorem, by default, the scope is the theorem, but adding the directive ‘**scope**=section’, the **knowledge** becomes available in the whole section.

If no scope is found using the above search, an explicit scope of the given name is used.

**export**= (not implemented) When using this directive, the knowledge will be (furthermore) written to another file, ready for being used in another document. In particular, the knowledge (in the other document) will point to the present one. The details on how this is supposed to work is to be specified.

**namespace**= Allows to change the namespace. In itself, this is useless. It has to be used in conjunction with new forms of `\kl`-like commands.

**now** requires the **knowledge** to be defined immediately. This may save one compilation phase. The drawback is that the **knowledge** cannot be accessed before the `\knowledge` command that has been introduced. It may help for modularity considerations. (for instance a **knowledge** is used inside a proof, it makes no sense to make it available elsewhere, and it is better style to locally define it). This is implicit if the `\knowledge` command happens in the preamble.

**also now** requires the **knowledge** to be defined immediately as well as delayed to the next compilation phase. This is in particular how auto references should be handled. See the use of `\knowledgenewvariant` for more examples.

### 3.3.3 General directives

We give here the list of display directives that are available without loading any sub packages. A certain number of Boolean directives are available without any options. These most of the time are used for typesetting the output. Each of these can be used as ‘bool=true’ (or shortly just ‘bool’), ‘bool=false’ or ‘bool=default’ (that leaves it in the default state, or the one determined by surrounding knowledges). The general boolean directives are the following:

**emphasize** forces the text to be emphasized using ‘\emph’,

**italic/up** forces/unforces italic (up does nothing in math mode),

**boldface/md** forces/unforces boldface (be it in math or text mode),

**smallcaps** forces small capitals,
**underline** forces the text to be emphasized using `\underline{}`,

**fbox** puts a box around the text,

**typewriter** puts in typewriter font (be it in math or text mode),

**ensuretext** guarantees that text mode is used (using the `\text` macro, thus in a way consistent with the surrounding style),

**ensuremath** guarantees that math mode is used,

`mathord`, `mathop`, `mathbin`, `mathrel`, `mathopen`, `mathclose`, `mathpunct` yield the corresponding standard \TeX\ spacing features in math mode,

- **mathord** for an ordinary mathematical object,
- **mathop** for a large operator (such as \( \sum, \Pi \), ...),
- **mathbin** for a binary operation (such as \(+, -, \) or \( \otimes \), ...),
- **mathrel** for a binary relation (such as \( =, <, \leq, \) ...),
- **mathopen** for an opening bracket, parenthesis, ...,
- **mathclose** for an closing bracket, parenthesis, ...,
- **mathpunct** for a punctuation symbol.

**lowercase** puts the content in lowercase,

**uppercase** puts the content in uppercase,

**detokenize** detokenizes the content, i.e., instead of executing it provides a string that displays it (this is useful for commands),

**remove space** removes the spaces from the text

**invisible** prevents the rendering of the knowledge.

The non-boolean general directives are the following:

**text=** `{text}` will execute the \LaTeX\ code `text` instead of the key used for calling `\knowledge`. For instance, `\knowledge{latex}{text=\LaTeX}` will typeset `\LaTeX` properly when used. Surrounding braces can be omitted if there are no commas. Be careful when linking to such knowledges, since the substitution of meaning will happen for all the knowledges linking to it, and this may not be the expected behaviour.

**link=** `{knowledge}` will continue searching the for linked knowledge. Surrounding braces can be omitted if there are no commas. This directive is often bypassed by the use of the optional argument of `\knowledge` defining synonyms or the `synonym` directive.

**link scope=** `{label}` will continue searching in the scope identified by the label. Surrounding braces can be omitted if there are no commas. If no directive `link=` is given, then the same key is searched for.

This directive is often bypassed by the use of the optional argument of `\knowledge` defining synonyms or the `synonym` directive.
synonym defines the knowledge as a link to the previously defined knowledge (in fact, the most recently defined that was not using synonym). For instance

\knowledge{Leslie Lamport}
  \{ref={https://fr.wikipedia.org/wiki/Leslie_Lamport}}
\knowledge{L. Lamport}{synonym}
\knowledge{Lamport}{synonym}

results in the two subsequent knowledge names to point to the first one.

style={knowledge style} will adopt the styling option of the knowledge style. Surrounding braces can be omitted if there are no commas.

wrap=\token \token will execute the macro \token with as argument the knowledge text before displaying it. For instance, wrap=\robustdisplay, (where \robustdisplay is a variant of \tl_to_str:n removing the trailing space) is used in this document for typesetting the commands.

3.3.4 Knowledge styles and the \knowledgestyle command

Styles are formatting pieces of information, as for knowledges, but that can be used by other knowledges. In some respect, this is very similar to macro directives (see below), but the difference lies in that styles are dynamically resolved, while macro directives are statically resolved. Styles in particular offer the access to some configuration features of the system. For instance, changing the intro style changes the way the \intro command is displayed. See below for some instances.

The central command is \knowledgestyle, that has the following syntax:

\knowledgestyle*{style name}{directives}

The optional star * permits to overload an existing style (otherwise, this results in an error). The directives follow the same structure as for a normal \knowledge command. When defined, a style can be used in a \knowledge command using the directives 'style=style name' (it will be used when a \kl command calls for the knowledge) or 'intro style=style name' (that will be used by \intro commands).

A certain number of default styles are also offered, that in particular includes warning styles. The list is as follows:

kl is the default style for macros using \kl. It can be modified dynamically using the 'style=' directive.
kl unknown and kl unknown cont are the default styles used when an undefined knowledge is met.

intro and is the default style for macros using \intro. It can be modified dynamically using the 'intro style=' directive.
intro unknown and intro unknown cont are the default styles used when an undefined knowledge is met.

3.3.5 New directives: the \knowledgedirective command

When defining knowledges, it is often the case that the same sequence of directives are used. Macro directives are here for simplifying this situation (see also \know-
\textbf{Hint.} This should not be confused with styles which offer another way to control the display.

\textbf{\texttt{ledgerdefault}} and \texttt{\textbackslash knowledgestyle}). This is achieved using the \texttt{\textbackslash knowledge\textbackslash directiven}-

\texttt{\textbackslash knowledge\textbackslash directiven}\{\texttt{name}\}[\texttt{optional parameter}]{\texttt{directives}}

After such a command has been issued, ‘name’ becomes a \texttt{\textbackslash directive} usable in \texttt{\textbackslash knowledge} commands, that amounts to execute the comma separated list ‘directives’. The newly created \texttt{\textbackslash directive} may receive a value, that is accessible as \texttt{#1} in ‘directives’. By default, it does not allow the redefinition of a directive. This can be forced using the optional \texttt{*}. The ‘optional parameter’ gives a default value. For instance:

\begin{verbatim}
\knowledge\texttt{\textbackslash directive}\{\texttt{highlight}\}[\texttt{brown}]{\texttt{color}={\texttt{#1}},\texttt{emphasize},\texttt{md}}
[...]
\knowledge{\texttt{notion A}}{\texttt{highlight}}
\knowledge{\texttt{notion B}}{\texttt{highlight}}
\knowledge{\texttt{notion C}}{\texttt{highlight}}
\knowledge{\texttt{important notion D}}{\texttt{highlight=red}}
[...]
\end{verbatim}

We shall now see \texttt{\textbackslash kl}\{\texttt{notion A}\}, \texttt{\textbackslash kl}\{\texttt{notion B}\}, \texttt{\textbackslash kl}\{\texttt{notion C}\}, as well as the \texttt{\textbackslash kl}\{\texttt{important notion D}\}.

yields

\begin{verbatim}
We shall now see notion A, notion B, notion C, as well as the important notion D.
\end{verbatim}

\subsection{\texttt{\textbackslash knowledgestyle} versus \texttt{\textbackslash knowledge\textbackslash directive}}

The two commands \texttt{\textbackslash knowledgestyle} and \texttt{\textbackslash knowledge\textbackslash directive} offer ways to systematize the writing of knowledges. These can seem redundant. This is not the case, and for understanding it, it is necessary to understand a bit the way the \texttt{\textbackslash knowledge} command works.

In general when a \texttt{\textbackslash knowledge} (or \texttt{\textbackslash knowledgestyle}) command is found, the directives are parsed and a new internal form of the \texttt{\textbackslash knowledge} command is written in the \texttt{\textbackslash kaux} file, that will be executed during the next compilation of the document. In this phase, some first operations are performed. For instance, in an \texttt{\textbackslash autoref} directive, an internal label name is constructed.

The postponed command is then executed during the next compilation phase (or immediately if we are in the preamble, or if the \texttt{\textbackslash now} directive is used). The execution effectively stores the knowledge in the system. This is only at that moment that the knowledge becomes available to be used by \texttt{\textbackslash kl} and similar commands.

When a \texttt{\textbackslash kl} command (or similar) is met, it is ‘executed’, and display informations are considered, and in particular styles are called.

Some consequences of this kind of this are as follows:
• **autoref** directives should not be used in the definition of a style, since this would mean that there would be one anchor point for all the knowledges that use this style. This is usually not the kind of behavior that we expect.

• configuring the default displays of the system (such as the intro style= in particular) has to be done through the style mechanism.

• styles use less memory than macros.

### 3.3.7 Default directives: the \knowledgedefault command

It may happen that a sequence of consecutive \knowledge commands have to share the same list of directives. The macro directives can help solving this issue. The default directives also go in this direction, using the \knowledgedefault-command:

```latex
\knowledgedefault*{directives}
```

When such a command is applied, then from that point, all \knowledge commands will use the given directives as default. This will stop when another \knowledgedefault command is met or the current group is closed. The optional star does not reset the default directives but simply add new ones.

### 3.4 The \kl command

#### 3.4.1 The standard syntax

The \kl command has one of the following syntaxes:

$$\text{\kl}(\text{optional scope})[\text{optional knowledge name}]\{\text{text}\}$$

or

$$\text{\kl}[\text{optional knowledge name}](\text{optional scope})\{\text{text}\}.$$

Its meaning is to search for the ‘optional knowledge name’ if present, or for ‘text’ otherwise. How this is exactly performed depends on the presence of the optional label. The search process is as follows:

- if an **optional label** is given, the knowledge is searched in the corresponding scope.

- otherwise, the stack of visible scope instances is processed through (starting from the inner most) until a knowledge of name ‘knowledge name’ or ‘text’, of namespace ‘default’ and this scope is found.

If the ‘knowledge name/text’ has not been found, the style ‘kl unknown’ (or similar styles, as defined by the unknown style= or unknown style cont=) is used, and the text displayed.

- Otherwise, the knowledge is executed. If it is a **link=** or **synonym** defined knowledge, the link is followed, and the process continues.

- Finally, all the definitions involved in the knowledge are processed, following a style= if defined, the knowledge is updated (essentially incrementing the counter of use), and the knowledge is displayed.

This general mechanism is used also by other commands that are variations around \kl such as in particular \intro.
3.4.2 The quotation notation

When activated, the quotation mode activates shorthand notations for the $\texttt{\textbackslash kl}$ and $\texttt{\textbackslash intro}$ macros. Possible syntaxes are as follows:

"text" uses the knowledge pointed to by ‘text’. Equivalent to $\texttt{\textbackslash kl\{\text\}}$.

"text@knowledge" uses the knowledge pointed to by ‘knowledge to display ‘text’. Equivalent to $\texttt{\textbackslash kl\{knowledge\}\{text\}}$.

"text@@scope" uses the knowledge pointed to by ‘text’ in scope ‘scope’ to display ‘text’. Equivalent to $\texttt{\textbackslash kl\{scope\}\{text\}}$.

"text@knowledge@scope" uses the knowledge pointed to by ‘knowledge in scope ‘scope’ to display ‘text’. Equivalent to $\texttt{\textbackslash kl\{knowledge\}\{scope\}\{text\}}$.

Activating the quotation notation is obtained using:

\texttt{knowledgeconfigure\{quotation\}} ,

and deactivating it is obtained using:

\texttt{knowledgeconfigure\{quotation=false\}}.

It can also be activated while loading the package.

It is sometimes the case that some packages do use the quote symbol, usually in some environment (this is the case of the $\texttt{tikzcd}$ environment). The knowledge package can be configured to deactivate always the quotation notation when entering the environment. This is obtained using the configuration option protect quotation= followed by a list of environments to be protected:

\texttt{knowledgeconfigure\{protect quotation=\{env1,env2,...\}\}}

Note that the braces surrounding the list of environments can be omitted if the list contains only one item.

There are nevertheless some situations in which one would prefer to use the original $\texttt{\textbackslash kl}$ notation:
• When nesting of \texttt{knowledges} is involved, or the \texttt{knowledge} includes the symbol ",",

• when \texttt{quotation} is deactivated (or not activated) because of a conflict

• in particular, this should be avoided in macros, in particular for the math mode, since these may be used one day or another in a \texttt{tikzcd} or similar environment for instance.

3.4.3 Variants of \texttt{\kl}, \texttt{\knowledgenewvariant}, \texttt{\knowledgevariantmodifier}

It may happen for several reasons that we may want to define new variants of the \texttt{\kl} macros, that essentially perform the same task, but are configured differently. Typical examples may be:

• several sets of \texttt{knowledges} may intersect but should use different \texttt{namespace},

• some \texttt{knowledges} involve macros and for this reason should be non-expanded even if the \texttt{\knowledge} command is not met,

• the \texttt{\knowledge} command should be called implicitly,

• activate or deactivate the warnings or messages in the \texttt{diagnose file}.

In fact, several macros in this document are instantiation of this mechanism. This is the case for for instance for \texttt{\intro}, \texttt{\phantomintro}, \texttt{\reintro} or \texttt{\mathkl} etc...

The macro for introducing a new \texttt{variant of \kl} is:

\texttt{\knowledgenewvariant\variant{variant directives}}

and is similar to the one for modifying the behavior of a \texttt{variant of \kl}:

\texttt{\knowledgesetvariant\variant{variant directives}}

These command define/modify a/\texttt{the macro \variant} that uses the same syntax as \texttt{\kl}. The \texttt{variant directives} consist of a comma separated list of directives as follows:

\texttt{namespace=namespace} declares in which \texttt{namespace} (a string) the knowledges are to be searched. This means in particular that the \texttt{\knowledge} concerned should be defined using the the proper \texttt{namespace=} directive.

\texttt{default style=, unknown style=, unknown style cont={list of style names}} declares the style name to be used (1) by default when the knowledge is found, (2) when it is not found for the first time, and (3) the subsequent times.

\texttt{style directive={directive names list}} defines a list (comma separated) of directives that can be used in a \texttt{\knowledge} command to modify the aspect (for instance, the \texttt{\intro} behavior is modified by the \texttt{intro style=} directive, while the \texttt{\kl} command is configured using the \texttt{style=} directive). If the \texttt{directives} do not exist, these are created.
auto knowledge={directives} declares that the use of \variant should automatically execute a \knowledge command, and what should be the directives it uses. See examples below.

unknown warning=true/false activates or deactivates the warnings when a knowledge is not found (for instance, these are deactivated in paper mode). True by default.

unknown diagnose=true/false activates or deactivates the corresponding messages in the diagnose file. True by default.

suggestion={directives} configures the directives to be suggested in the diagnose file when the knowledge is unknown.

PDF string={code} gives a substitute text for hyperref to use for producing the bookmarks. This code has to be expandable. The code may use three parameters; \#1 is the main text of the command, \#2 is the optional parameter, and \#3 is the scope. The macro \IfNoValueTF of the package xparse can be used to test if the second and third arguments are present. By default, the code is \{\#1}. Note that the star syntax cannot be used in this context. If the expected result cannot be achieved using this directive, the less convenient macro \texorpdfstring of the hyperref package should be used.

The second feature is to use modifiers. These correspond to the stared version of the command. For instance, one expects \intro*\kl to reduce to \intro. For this, one has to declare explicitly the reduction using:

```latex
\knowledgevariantmodifier{stared sequence}\variant
```

in which the \textit{stared sequence} is of the form ‘\texttt{variant1*variant2*...*variantk}’. This sequence is declared to reduce to \variant. For instance, \knowledgevariantmodifier{\intro*\kl}\intro declares ‘\texttt{\intro*\kl}’ to reduce to ‘\intro’.

### 3.4.4 Examples of variants of \kl

The best way for introducing new variants is to look at examples. We provide two of them now. The first one is the configuration of the \kl and \intro commands as defined in the package. The second one is the code used in this documentation for displaying macros, defining the macros \cs and \csintro.

The \textbf{configuration of} \kl and \intro It is also interesting to see this code since it gives more ideas on how to modify the standard behaviour of these commands correctly.
Displaying control sequences  The second code example is used in this document (the documentation of the package) and consists of two macros \cs and \csintro which have the following semantics:

- these have the same syntax as \kl and \intro respectively,
- these are used to display control sequences without executing it,
- if \csintro is never used, it appears in black,
- is \csintro is used, then it is in color blue, and the calls to \cs are in dark blue, and furthermore, the \cs calls possess an hyperlink to the call to \csintro.
- no \knowledge command is necessary, and no warnings are issued.
Several things can be noted about this code:

- the directives `detokenize` and `remove space` prevent the execution of the argument, and instead display its name, this is important since the argument is a control sequence,
- the directives `typewriter`, `up` and `md` give a uniform aspect (no italic, no boldface) to the result in all contexts,
- the `namespace` is set to be different from the default one, avoiding possible clashes with `\kl`,
- when a `\csintro` command is met, the corresponding `\knowledge` command is automatically issued, in particular with `scope=document` for guaranteeing the visibility of each command everywhere in the document,
- the `also now` directive is necessary for the compilation to (possibly) stabilize in two iterations, since it uses the proper `\label` already at the first iteration (without `also now`, it would be performed on the second one only, and with just `now`, it would be visible only by the uses after the introduction).
- warnings and diagnose information is explicitly eliminated.
3.5 Scoping

3.5.1 Principles of scoping

When writing long documents, one often wants knowledges to be isolated in some subparts. For instance, one may want a temporary definition in a proof to not leak elsewhere in the document where the same term could be used with a different meaning. Some definitions may be only meaningful in, say, the current section/part.

Two separate things have to be understood: how to define knowledge in a given scope (and create scopes), and how to access knowledge from a given scope.

Accessing knowledge attached to a given scope  This can be done directly either using the parenthesis notations of $\kl$ and the second $@$ of the quotation notation:

$\kl(scope\ name){knowledge}$ or $\kl(scope\ name)[knowledge][displayed\ text]$

"knowledge@scope" or "displayed\ text@knowledge@scope"

It works also for $\intro$ and with double quotes.

Another option is to import the scope locally, using:

$\knowledgeimport{scope\ name\ 1,scope\ name\ 2,\ldots}$

After this command, the knowledges will be searched automatically in the imported scopes. The import stops at the end of the current scoping environment.

Attaching knowledge to a given scope  This can be done directly using the $scope=$ directive, for instance in:

$\knowledge{knowledge}{scope=scope\ name, directives}$

or, this is obtained usint the ‘|’-notation using ‘@’ :

$\knowledge{directives} | knowledge@scope\ name\ 1$

| synonym@scope\ name\ 2

$\ldots$

The other possibility is to define a knowledge inside a $\begin{scope}$ environment:

$\begin{scope}$

$\知识{knowledge 1}{directives}$

$\ldots$

$\end{scope}$

In such a code, the knowledge defined is automatically visible in the environment, and from outside, using the scope name $\label$. Indeed, the $\label$ is overloaded for doing automatically a $\knowledge$ command.

In fact, it is possible to do even more: other environments can be defined to behave like $\scope$. 

28
3.5.2 Scoping by examples

**Explicit scoping** consists in attaching a precise scope name to a knowledge using the `scope=` directive:

```
\knowledge{thing}{scope=s1,color=red}
\knowledge{thing}{scope=s2,color=green}
```

Here, "thing" and \kl{thing} are unknown. But "thing@@s1" and \kl(s1){thing} are in red, and "thing@@s2" and \kl(s2){thing} are in green.

The `|`-notation can also be used for explicit scoping. This is convenient, in particular for having synonyms in different scopes:

```
\knowledge{color=red}
| abelian group
| abelian groups
| Abelian groups
| group@abelian
| groups@abelian
| Groups@abelian
```

Here, general "groups" are not defined but "groups@@abelian" are, and correspond to "abelian groups".

```
\begin{scope}\knowledgeimport{abelian}
Here, all "groups" here are abelian.
\end{scope}
```

Scopes can also be attached to areas in the code. It is convenient to use the usual `\label` command to name them (though a priori two different spaces of naming are used).

```
% We declare first in the preamble the environments that can have % knowledges attached to them.
\knowledgeconfigureenvironment{theorem,lemma,proof}{}

% and now in the main body of the document.
\begin{theorem}\label{theorem:main}
\knowledge{rabbit}[rabbits]{notion}
In every hat, there is a \kl{rabbit},
\AP in which a \intro{rabbit} is a small animal with long ears.
\end{theorem}
Here a "rabbit" is an unknown knowledge.

But "rabbits@@theorem:main" point to Theorem \ref{theorem:main}.

```
\begin{proof}\knowledgeimport{theorem:main}
Now, "rabbit" is hyperlinked to Theorem \ref{theorem:main}.
```

```
\end{proof}
```

3.5.3 What is the structure of scopes in a document

To start with, one needs to understand what are the possible scopes. Scopes are aggregation of zones in the document.

- By default, all the body of the document belongs to a scope called ‘document’. The user can open new scopes using the \texttt{scope} environment:

\begin{scope}
  \texttt{local notion}\{color=green\}
  Here is a \texttt{local notion} that appears in green.
\end{scope}

But here the \texttt{local notion} is undefined.

Note that scoping is independent from the grouping mechanism of \LaTeX. The user can also declare environments such as \texttt{lemma}, \texttt{theorem}, \texttt{remark} or \texttt{proof} to behave like \texttt{scope}. This is achieved using using \texttt{knowledgeconfigureenvironment} command.

- The use of the \texttt{scope} configuration option goes one step further, and attaches scopes to sections, subsections, itemize, items, and so on. But be cautious, this feature, though working, may cause some compiling document to not compile anymore if some weird (and unnatural) nesting of scopes are used (this is the case for instance when using \texttt{bibitem} and \texttt{thebibliography}, and this has to be corrected by hand).

3.5.4 How is chosen the scope of a knowledge?

In general, when a \texttt{knowledge} command is used, the system tries to figure out what should be its scope:

- If the command occurs in the preamble, then the default scope will be ‘document’.

- Otherwise, the information is searched for in the \texttt{stack of visible scope instances} which means that the \texttt{knowledge} will be defined at the level of the innermost surrounding scope that ‘attracts knowledges’. If the \texttt{scope option} is not activated (and the user did not perform its own configuration), this is the inner most \texttt{scope} environment (or similar environment if \texttt{knowledgeconfigureenvironment} has been used), or ‘document’ if the declaration is not in the scope. If the \texttt{scope option} is used, this will be the innermost lemma, proof, or theorem in the context.

- This default behavior can be modified using the \texttt{scope=} directive. The \texttt{scope=} directive can be followed with a scope level, such as ‘section’, ‘subsection’, ‘chapter’ or ‘itemize’ (in particular in combination with the \texttt{scope option}), that will be looked for in the current context and will receive the \texttt{knowledge}. The \texttt{directive} can also be followed by a label name, and the active scope at the moment of this label will be used.
The following code (that requires the scope option for being functional) should be self explanatory:

\section{First section}
\label{section:first}
\knowledge{one}{scope=section,color=green}
\knowledge{two}{scope=some label,color=green}

\begin{scope}\label{some label}
  \knowledge{one} and \knowledge{two} are defined.
\end{scope}
Here \knowledge{one} is defined but \knowledge{two} isn’t.

\section{Second section}
Here neither \knowledge{one} nor \knowledge{two} is defined. However, I can still use them using \knowledge{section:first}{one} and \knowledge{some label}{two} (or "one@@section:first" and "two@@some label", or using the \knowledgeimport{section:first}).

3.5.5 Naming scopes: the \knowledgeimport, \knowledgescope and label commands

It is often the case in a text, that one has to locally break the nesting structure of a document, and refer to a object local in an environment. For instance, a comment may refer to a variables/concept that has been locally used in the proof. The knowledge provides suitable mechanisms for complex referencing of scopes. Let us explain this through an example:

% We declare first in the preamble the environments that use knowledge.
\knowledgeconfigureenvironment{definition}{knowledge=attracts} [...]
\begin{definition}\label{somewhere}
\knowledge{something}{notion}
Here, \intro{something} is a notion internal to the definition.
\end{definition}

Note here that what is important is the location of the knowledge command, irrespective of the location of the intro command.

The \label command is used to name the scope. In fact, the real command is

\knowledgescope{scope name}

which associates a scope name to the surrounding environment (providing it has been declared possible to do it using \knowledgeconfigureenvironment). The standard \LaTeX command \label is overloaded and performs implicitly a call to \knowledgescope (this behavior can be deactivated/reactivated using the label scope={true,false} directive). The result is that the same string of characters
can be used in order to name the scope, and at the same time is used as a standard \LaTeX label.

Something important is missing so far: one rapidly wants to access to knowledges that do not exist in the current scope. For instance, a notion is used in a section of a document, and one would like to refer to it in the introduction. Another case is that of a notion or a mathematic variable that is introduced in the statement of a theorem, and should be accessible inside the proof. There are essentially two ways to access such distant knowledges: either use the \texttt{\kl(label){text}} command (or the equivalent "@@@" notation), or use the \texttt{\knowledgeimport} command. We describe the second possibility now. The syntax is:

\texttt{\knowledgeimport{label}}

The result is that the knowledges in the scope identified by the label are now accessible until the closure of the current scope.

For instance:

\begin{verbatim}
\knowledgeconfigureenvironment{theorem,proof}{}
[...]
\begin{theorem}\label{theorem:1}
\knowledge\alpha{autoref,color=red}
Let $\intro\alpha$ be an integer [...]
\end{theorem}
[...]
\begin{proof}
\knowledgeimport{theorem:1}
But now $\kl\alpha$ points to its definition.
\end{proof}
\end{verbatim}

3.5.6 Managing scoping environments

The user can also declare an environment to behave like scope using the command \texttt{\knowledgeconfigureenvironment}, as well as adapt some of its characteristics using scope directives.

\texttt{\knowledgeconfigureenvironment{environments}{scope directives}}

For instance:

\begin{verbatim}
\knowledgeconfigureenvironment{lemma,theorem,fact,proof}
{knowledge=attracts}
\end{verbatim}

will induce the corresponding environments to have internal knowledges.

Most of the times, it is not necessary to use scope directives.

\textbf{Remark 1} Note that (in the current implementation) it is necessary to use the commands \texttt{\begin} and \texttt{\end}. Hence \texttt{\proof...\endproof} would not trigger a scoping environment while \texttt{\begin{proof}...\end{proof}} would.
The *scope directives* are low level and advanced features. These should not be used in general. The list is the following:

- **scope**=`true/false` tells whether an environment should induce a scope. For the moment, this is not used (as soon as configured, it always behaves like a scope).
- **label**=`none/accepts` tells whether a `\label` command can refer to an instance of this area.
- **environment**=`true/false` should be set to true if the scope has to be opened whenever an environment of same name is opened using the `\begin` and `\end` commands of *LATEX*.
- **autoclose**=`true/false` means that the closure is triggered by another event (closure of another enclosing instance, or pushing of an area that requires its closure). It should be true for *LATEX* environments, and false when configuring, e.g., `\section` to open an scope (since the end of the section is automatic: when another section is opened, or some higher level sectioning command).
- **parents**=`{area1,area2,...}` takes a comma separated list of areas that are allowed as parent. For opening the area, some enclosing instances may be automatically closed for reaching such a parent (if their **autoclose** directive is set to true).
- **push code**=`{code}` defines the code to be executed when the area is pushed (each time, these are added).
- **pop code**=`{code}` defines the code to be executed when the area is popped (added too).
- **occurrences**=`once/multiple/recursive` can be one of ‘once’ if the area can only have one instance in the document, ‘multiple’ if there can be several instances, but not nested, and ‘recursive’, if there is no restriction.
- **forces**=`area` requires a specific area as an ancestor of this area. This ancestor is implicitly pushed if necessary.

## 3.6 Error handling

By default, the *knowledge* package tries to not stop the compilation unless a serious problem has been found. In particular, it is possible to write an entire document using `\intro` and `\kl` commands or the *quotation notation* without ever introducing a knowledge, and only in the end provide this information. This is a feature: as opposed to normal macros, not defining a knowledge should not stop the real work, which is the writing of the document.

Very often there is some undefined knowledge. Such knowledges are displayed using `kl unknown` and `kl unknown cont` styles when issued by `\kl`; using `intro unknown` and `intro unknown cont` when issued by `\intro`. The detail of the problems are then gathered in the *diagnose file*. 

3.7 The diagnose file

The diagnose file is a file that is created when the knowledge package is used (note that another file, jobname.kaux is also created by the knowledge package, for internal use). It enormously eases the use of the package, and it is important to look into it when finalizing a document. It gathers a certain number of informations, that can be warning, code to be used, or simply information. This file has the name of the tex document with the extension .diagnose. Its content is divided into clearly identified parts. Depending on the used options, some of these parts may appear or disappear.

Undefined knowledges in this section are listed all the knowledges that have been unsuccessfully searched for. These are given in lines either of the form

\knowledge{suggested directives}
  | undefined knowledge/@scope/
  :

or of the form

\knowledge{undefined knowledge}{suggested directives}

Switching from one mode to another is obtained using the configuration directive \texttt{diagnose bar}={true,false} (default is true). The intent is that copying the content of this section to the document itself will solve all problems of undefined knowledges. It is an efficient way, when one has written a document without caring so much about knowledges to copy the content of this section, and then modify it/reorganize it, in order to suit ones purposes. By default, no suggestion is offered, or notion is suggested if the notion directive has been used. Suggestion can be automatically configured using the \texttt{suggestion=} directive of the macros \texttt{knowledgenewvariant} and \texttt{knowledgesetvariant}.

For instance, using:

\texttt{\knowledgesetvariant\kl\{notion\}}

the directive notion is suggested for more directly copying the content.

Autoref not introduced This section lists all knowledges that were declared using the autoref directive (this can be the case indirectly using, e.g. notion), but have not been introduced in the document. When a document reaches its final states, this section should be empty. Usually, one should add the corresponding \texttt{intro} or \texttt{phantomintro} command somewhere in the text.

Autoref introduced twice In this section, all knowledges that were declared using the autoref directive and introduced using \texttt{intro} or \texttt{nointro} more than once are listed. When a document reaches its final states, this section should be empty. Consider using \texttt{kl} or \texttt{reintro} for solving the problem.
Note that this may be caused by an \intro used in some title (and repeated in the table of contents).

By default, the diagnose file does not give the file and the line of the messages. This can be activated using the diagnose line boolean option:

\knowledgeconfigure{diagnose line=true}

By default, the diagnose file gives suggestions to be used with the normal \knowledge syntax. A ‘|’-notation suggestion can be activated using:

\knowledgeconfigure{diagnose bar=true}

3.8 Other packages

3.8.1 The xcolor option

The xcolor option is used if one wants to change colors. It is good to always load it since it also triggers coloring for debugging. It triggers colors in the warning styles that can be useful in debugging. It also offers two new directives:

- color= where in ‘color=’name’, name is a color description following the syntax of the xcolor package.

- cyclic color similar to ‘color=’, but selects the color automatically in a a cyclic list of colors. This can be convenient for debugging. The cyclic list of colors can be chosen using the configuration directive cyclic colors=:

  \knowledgeconfigure{cyclic colors={color1,color2,...}}

Note that no spaces are allowed between colors, and that at least two colors are required.

The default cyclic color list is:

{red,green,blue,cyan,magenta,yellow,gray,lime, olive,orange,pink,purple,teal,violet}

colorbox= surrounds the text with a colorbox of given color (following the syntax of the xcolor package).

Loading the package before is necessary for changing the options of the xcolor package (for instance for using svgnames).

3.8.2 The hyperref option

Activating the hyperref option  The hyperref option loads the hyperref and triggers a certain number of link-related features. This is done either by the command:

\Hint. The hyperref surrounds by default links by boxes that are graphically heavy (this are visible in some viewers, and not in some others): this is deactivated by the knowledge package using the hidelinks option of hyperref.
or by loading the `hyperref` before the `knowledge` package.

The directives activated by the package are:

- `url=` for hyperlinking to an external document
- `ref=` for hyperlinking inside document
- `protect link` is a boolean for protecting from the creation of nested hyperlinks,
- `autoref` for relating objects with their definition
- `autorefframe` similar, and used implicitly for math

The package comes also with the configuration directive `hyperlinks=` which is a boolean deactivates or reactivates the links.

**Functionnalities triggered by the `hyperref` option**

- `ref= {label}` puts an hyperlink pointing toward a label inside the document (the braces can be omitted when there is no comma).
- `protect link` disables the inside hyperlinks,
- `url= {url address}` puts an hyperlink to an (external) url (the braces can be omitted when there is no comma).
- `autorefframe` activates the ability to introduce once, use several times an instance.

This is very convenient when writing scientific documents with many notions.

This is the basic directive activating the features of the `intro` command.

The syntax of `intro` is the same as for `kl`:

```
\intro[optional knowledge name]{knowledge name}
```

**See \AP below for improving the result.**

A typical use looks as follows:

**Hint.** You may have to use `\` instead of `~` in url's addresses.

**Hint.** It is usually easier to use the `notion` directive than simply the `autoref` directive. Its use it already configured.

**Hint.** Though the `intro`-command can be used in the title of, e.g. sections, without any errors, this may cause a warning when a table of contents is used: the command is executed twice, once in the table of contents, and once in the document itself.
In this document, we will see the very important notion of \textit{"houses"}.

Let us define a \textit{"house"} to be a building that functions as a home.

The variant \texttt{\textbackslash intro*} makes the next \texttt{\textbackslash kl} command behave like \texttt{\textbackslash intro}. This is useful in particular in math mode:

\begin{verbatim}
\newcommand{\monoid}{\kl[\monoid]{\mathcal M}}
\end{verbatim}

Let now \texttt{\textbackslash intro*\monoid} be a monoid.

Remember now who is \texttt{\monoid}.

The \texttt{\textbackslash phantomintro} version:

\begin{verbatim}
\phantomintro\{knowledge\}
\end{verbatim}

takes a \texttt{knowledge}, and introduces it at the current location, without displaying anything. This is behaves like an invisible intro, i.e., essentially an abbreviation for \texttt{\textbackslash intro\{knowledge\}}. This can be used as a workaround in environment like \texttt{align*} that do not allow the use of labels (see Section 4.5).

The \texttt{\textbackslash nointro} command:
\nointro{knowledge}

does not display anything and silently prevents the knowledge from issuing warnings because it is not introduced.

The $\texttt{reintro}$ command:

$\texttt{reintro[optional knowledge]}{knowledge}$

is displayed as for $\texttt{intro}$, but without being an anchor for hyperlinks, and without counting as a real $\texttt{intro}$. It is used if there are for some reason several places that should look like an introduction (typically in the same paragraph), but count as a single target. There is a variant $\texttt{reintro*}$ that makes the next $\texttt{kl}$ command behave like a $\texttt{reintro}$ (similar to $\texttt{intro*}$ with respect to $\texttt{intro}$).

Knowledge that use this directive can be parameterized by modifying the style $\texttt{intro}$.

For modifying the display of knowledge introduced by $\texttt{intro}$, there are new directives:

$\texttt{intro style=}$ that takes the name of a style as argument. This style will be used when the knowledge is used in a $\texttt{intro}$ or $\texttt{reintro}$ command.

$\texttt{autoref target}$ declares the knowledge to be the target of the autoref (this is implicit when using $\texttt{intro}$).

$\texttt{autoref link}$ requires a link to the target of the autoref to be produced (this is implicit when using $\texttt{kl}$).

See the use of $\texttt{knowledge set variant}$ for examples of configuration.

**The autoreffhere directive** The $\texttt{autoreffhere}$ directive silently introduces an anchor point at the location of the $\texttt{knowledge}$ command invoking it. Uses of $\texttt{kl}$ commands will be hyperlinked to this location.

In some sense, an $\texttt{autoreffhere}$ directive can be understood as the sequence of a $\texttt{autoreff}$ directive that would be immediately followed by the corresponding $\texttt{intro}$ command. This is a bit better since using $\texttt{autoreff}$ in the body of the document requires three phases of compilation (two only if in the preamble). However, the $\texttt{autoreffhere}$ directive does only require two (as for normal labels).

In fact, this $\texttt{autoreffhere}$ directive is what is used underneath when introducing mathematical variables, and should be used for implementing similar behaviors.

**Using anchor points** The directives $\texttt{autoreff}$ and $\texttt{autoreffhere}$ use underneath the $\texttt{hyperref}$ package. This means that it puts a label at the place of the $\texttt{intro}$ command, and then points to it. However, the semantics in this case, is to jump to the beginning of the surrounding ‘region’. If the $\texttt{intro}$ happens in a ‘section’ (but not inside a theorem-like environment) then the $\texttt{kl}$ command will point at the beginning of the section, possibly 10 pages above the definition itself.
The standard solution in the \texttt{hyperref} package is to use the \texttt{\phantomsection}. This means defining \texttt{anchor points} in the document that will be the target of hyperlinks.

We offer here new commands for helping using this feature:

\texttt{\AP} declares an \texttt{anchor point} at the left of the current column, at the height of the current line. If the configuration option \texttt{visible anchor points} is set (and this is the case by default), a mark will show the precise location of the target. Be careful: it does not work in some situations, like for instance inside the optional argument of an \texttt{item} command (but this is ok elsewhere in an itemize environment), or inside a some macros in mathmode (e.g. fractions). In the particular case of \texttt{item}, one should use instead:

\texttt{\itemAP} Similar to \texttt{\AP}, but to be used instead of an \texttt{item}.

Usually putting an \texttt{\AP} (a standard command of the \texttt{hyperref}) at the beginning of every paragraph, and replacing \texttt{\item} by \texttt{\itemAP} in itemize-like environments is most of the time good and safe option.

For instance:

\begin{verbatim}
\AP
In order to describe what is a \texttt{\kl{monoid}}, let us us first define a \texttt{\intro{product}} to be an associative binary operator, and a \texttt{\intro{unit}} to be [...]
\end{verbatim}

\begin{description}
\itemAP[A \texttt{\intro{semigroup}}] is a set equipped with a \texttt{\kl{product}}.
\itemAP[A \texttt{\intro{monoid}}] is a \texttt{\kl{semigroup}} that has a \texttt{\kl{unit}}.
\end{description}

yields

\begin{itemize}
\item In order to describe what is a monoid, let us us first define a product to be an associative binary operator, and a unit to be [...]
\item A semigroup is a set equipped with a product.
\item A monoid is a semigroup that has a unit.
\end{itemize}

One can check that the different knowledges are properly hyperlinked, and that precise targets are the one described by \texttt{\AP} and \texttt{\itemAP}. For helping debugging the anchor points, these are by default made visible as (red) corners on output. When the \texttt{knowledge} package is loaded with the \texttt{paper} option this graphical help disappears. This can also be desactivated using:

\begin{verbatim}
\knowledgeconfigure{visible anchor points=false}
\end{verbatim}
3.8.3 The makeidx option

Activating the makeidx option  The makeidx option loads the makeidx package and triggers a certain number of link-related features. This is done either by the command:

\usepackage[makeidx]{knowledge}

or by loading the makeidx before the knowledge package.

Features  When activated, it becomes possible to trigger the \index command when a \kl command is used. The following directives are to be used:

index= is the text typeset in the index. It uses the standard syntax of the \index command. By default, it is the knowledge name itself. You can use the full syntax of \index in it, i.e. using ‘!’ and ‘@’.

index key= takes as argument the index key: a text that is used for identifying the index entry (usually an accent free version of it). You can use ‘!’ in it, as long as it does not clash with index= in order to avoid clashes.

index parent key= makes the index entry be a subentry of the given main index entry (a replacement of ‘!’). Once more, it should not clash with index= and index key=.

index style= is followed by a token (without the scape character) that will be used for displaying the number (e.g. \textbf). Usually, this is to be used in order to typeset in a particular manner the knowledges in the index when introduced. Thus, by default, the \intro, \reintro and \phantomintro command use the command \knowledgeIntroIndexStyle. Hence, you can use for instance:

\def\knowledgeIntroIndexStyle#1{\fbox{#1}}

3.9 Dealing with math

This part is under development.

3.10 Fixes

In this section, we present some fixes that have been added to help the user solve problems.

Hyperref and twocolumn  It happens that the hyperref and two-column mode yields a fatal error. This happens when a link spans across the boundary between two pages. This is an issue which is not related to the knowledge package, but becomes severely more annoying when more links have to be used. A workaround can be tried by using using
I do not know to which extend it is compatible with various classes...

3.11 Predefined configuration

3.11.1 The notion directive

The configuration option notion is activated using:

\knowledgeconfigure{notion}

It automatically configures a directive notion which is an autoref displayed properly:

- In paper mode, the intro commands (not in math mode) are emphasized, while the kl commands are displayed as normal. It has the aspect of a normal paper.

- In electronic mode and composition mode (with the xcolor package), notions are furthermore typeset in blue when introduced, and in dark blue when used. Without the xcolor package, underlining draw the attention to the knowledges (not in math mode).

The behavior of the notion directive is to activate autoref, and to configure the following two styles:

- the style notion is used for normal use,

- the style intro notion is used for introduction.

A typical document using notion could start by the following commands:

\documentclass{article}
\usepackage{xcolor}
\usepackage[hidelinks]{hyperref}
\usepackage[electronic]{knowledge}
\knowledgeconfigure{notion}
[...]
\knowledge{some text}{notion}

Then the paper is displayed in a colorful way.
4 Some questions and some answers

4.1 How to compile?

As usual with \LaTeX, a certain number of compilation phases are necessary for reaching a document in final form. The problematic point is of course the use of labels, and in particular the \texttt{intro} command. When it is used, and all the \texttt{knowledge} commands are in the preamble, then two phases are necessary. When \texttt{knowledge} commands are used in the body of the documents, then one extra phase is required, meaning three with \texttt{autoref} definitions. This is also the case when scoping is used.

4.2 Problem with \texttt{\item} parameters

The use of \texttt{\AP} inside the optional parameter of \texttt{\item} does not work. Do not use \texttt{\AP} inside the optional argument of \texttt{\item}, and rather use the command \texttt{\itemAP}.

Argument of \texttt{\kl} has an extra \\'). This is a problem of using optional parameters inside optional parameters such as in \texttt{\item[\kl[\text{test}]{Test}]} . You can surround the content of the optional parameter by two level of curly braces as in \texttt{\item[{{\kl[\text{test}]{Test}}}]}} . The notation "\ldots" does not have this issue.

4.3 Knowledges and moving arguments (table of contents, \ldots).

The use of \texttt{\kl} does not work in (e.g.) the table of content. When the \texttt{knowledge} name contains expandable macros, or accentuated letters, then these are not copied in the table of content as the exact same text, but are expanded/translated. Thus, when the table of content is displayed, the \texttt{\kl} command complains of not knowing the \texttt{knowledge}. For instance\footnote{with \texttt{\usepackage[utf8]{inputenc}} and, for instance \texttt{\usepackage[T1]{fontenc}} for the accents.}: 
will result in that both knowledges are considered unknown in the table of contents. For the first one, this is due to the expansion of \Ltwo. For the second, this is due to an implicit translation of the accentuated letter into an internal sequence of commands (for instance ‘é’ is translated into the internal sequence ‘\IeC{"e}’).

Some solutions are as follows:

- Make the macros non-expandable, for instance using \newrobustcmd (of the etoolbox package) or \NewDocumentCommand (of the xparse package, with a different handling of arguments) instead of \newcommand. Hence:

\newrobustcmd\Ltwo{\ensuremath{L^2}}

- Using an equivalent text that does not have the problem:

\knowledge{\'etale topology}{link=\'etale topology}

- Both problems can be solved using synonyms/links that have no problem. For instance:

\knowledge{Ltwo-space}{link=\Ltwo-space}
\knowledge{etale topology}{link=\'etale topology}

- Other solutions? None so far. I am trying to systematize the treatment of these problems.
Using \texttt{\texttt{\texttt{\texttt{introt}}}} in a section title causes introducing the knowledge twice. Do not use \texttt{\texttt{introt}} in titles, but rather \texttt{\texttt{reintro}}. If you want the section to be the target of the \texttt{knowledge}, then put after the section a \texttt{\texttt{pantomintro}} command.

\begin{tabular}{|c|c|}
\hline
\texttt{Problematic code} & \texttt{A solution} \\
\hline
\texttt{\section{On \texttt{introt} topology}} & \texttt{\section{On \texttt{reintro} topology}} \\
\texttt{\phantomintrot \texttt{topology}} & \\
\hline
\end{tabular}

\section{On \texttt{reintro} topology}

\subsection{Problems with \texttt{tikzcd} and other issues with the quotation notation}

The package \texttt{tikzcd} uses (heavily) the quotes. Thus, it conflicts with the quotation notation. Some other packages may do the same. For solving this issue, the only thing to do are:

- be sure to load these packages before \texttt{knowledge}, or at least be sure that the quotation notation is not active when you do so, and
- to temporarily deactivate the quotation notation when in a context where the package may use the quotes.

This can be done either explicitly using before each figure:
\begin{verbatim}
\knowledgeconfigure{quotation=false}
\end{verbatim}
and after the figure:
\begin{verbatim}
\knowledgeconfigure{quotation=true}
\end{verbatim}

Another possibility is to force some environment to deactivate systematically the quotation notation when used. For instance
\begin{verbatim}
\knowledgeconfigure{protect quotation={tikzcd}}
\end{verbatim}
will deactivate the quotation notation in all the \texttt{tikzcd} environments.

\section{Problems with \texttt{amsmath}}

The \texttt{introt} command does not work in \texttt{align*} or similar environments

It happens that in stared environment (i.e., unnumbered), the package \texttt{amsmath} deactivates the labels. As a consequence the command \texttt{introt}, which internally uses \texttt{label} (at least so far), does not work. For the moment, there is no real solution, but a workaround which consists in introducing the knowledge before the incriminated environment using \texttt{\phantomsection}, and then use \texttt{\reintro} inside the environment. Imagine for instance a command \texttt{\SomeCommand}, that inside uses \texttt{\kl\This}[\Somecommand \texttt{]}], then:

\begin{verbatim}
\begin{align*}
\texttt{\introt}\SomeCommand \\
\end{align*}
\end{verbatim}

\begin{verbatim}
\begin{align*}
\texttt{\phantomsection}\SomeCommand \\
\texttt{\reintro}\SomeCommand \\
\end{align*}
\end{verbatim}
4.6 Hyperref complains

A fatal error occurs in twocolumn mode. A workaround is to use \texttt{\texttt{\texttt{knowledge\configure\{fix hyperref twocolumn\}}}.

4.7 Incorrect display

4.7.1 Incorrect breaking at the end of lines (in Arxiv for instance)

It may happen that some hyperlinks generated by \texttt{knowledge} are not broken properly at the end of lines. This is an issue with the \texttt{hyperref} package. This happens in particular for files compiled by the Arxiv system while the file on the local computer was not having any problem. A workaround is to use the \texttt{breaklinks} option of \texttt{hyperref}. If you need this for Arxiv, then you also have to force the use of \texttt{pdflatex} (because the \texttt{breaklinks} option does not work if compiled via the ancestral sequence TEX→DVI→PS→PDF). This can be obtained by adding \texttt{\texttt{\texttt{pdfoutput=1}}} within the five first lines of the preamble.

The preamble thus looks like:

\begin{verbatim}
\documentclass{[...]}  
\pdfoutput=1  
[...]  
\usepackage[breaklinks]{hyperref}  
[...]  
\usepackage{knowledge}  
[...]  
\end{verbatim}

4.7.2 Red boxes around links

This is an annoying feature of the \texttt{hyperref} package to surround all links by red boxes (that may appear or not depending on the viewer). This is very heavy in document with many links. The solution is to load the \texttt{hyperref} package with the \texttt{hidelinks} option. Hence the preamble may look like:

\begin{verbatim}
\usepackage[hidelinks]{hyperref}  
\usepackage{knowledge}  
\end{verbatim}

4.8 Problems with scope

4.8.1 Problems in combination with \texttt{\texttt{\bibitem} and \texttt{thebibliography}}

The \texttt{scope} option of the package triggers some analysis of the code, and restrains the structure of the code (in particular, this is because \texttt{scopes} have to be nested, and thus some not so well nested parts of \LaTeX{} yield errors). In particular, the \texttt{scope} option does not allow to have a \texttt{section} command inside a list. However, this is what does the environment \texttt{thebibliography}, yielding a scoping error.

A simple hack to treat this situation:
The result is to revert to the original version of the macro `\section`, which does not make any structural test, and then reactivate the modified version of the command.

Another solution is to reconfigure the environment `thebibliography` using in the preamble:

\begin{verbatim}
\ScopeConfigure{thebibliography}
{push code=\let\section\SUPERsection, \pop code=\let\section\NEWsection}
\end{verbatim}

\section{Editors}

\subsection{Emacs editor and quotes}

The \textit{AucTeX} mode in \textit{Emacs} binds the quote symbol to other characters, cycling through ‘‘, ”, and “”. This is not convenient when using the \texttt{knowledge} package.

This behavior can be deactivated temporarily using:

```
M-x local-unset-key RET " RET
```

or definitively using:

```
(defun my-hook () (local-unset-key "\""))
(add-hook 'LaTeX-mode-hook 'my-hook)
```

Alternatively, this can be changed so as to cycle through ”, ‘‘, and ””, which is slightly more convenient than the default. This is achieved by customizing \texttt{TeX-quote-after-quote}:

```
M-x customize-set-variable RET TeX-quote-after-quote RET y
```

\section{Others}

If other kind of problems occur, report them to thomas.colcombet@irif.fr.
5 Resources

5.1 List of commands

\AP introduces an anchor point.
\intro searches for a knowledge and put an anchor to it (to be used with the
autoref directive).
\kl searches for a knowledge and displays it accordingly.
\knowledge defines new knowledges.
\knowledgeconfigure configures the package.
\knowledgedirective defines a new directive.
\knowledgedefault declares the default directives to be automatically used in
\knowledge commands.
\knowledgeimport gives access to knowledges existing in other scopes.
\knowledgenewvariant defines a new variant of \kl.
\knowledgesetvariant configures a variant of \kl.
\knowledgestyle defines a new style.
\knowledgevariantmodifier declares a meaning of * in variants of \kl.
\nointro declares that the knowledge will never be introduced (does not work
properly yet).
\phantomintro performs an invisible \intro.
\reintro uses the display style of \intro without introducing an anchor.

5.2 List of environments

export (not implemented) requires exportation of the content.
import (not implemented) declares external resources.
scope Defines a scope in which knowledges are internal.

5.3 List of directives (to use with \knowledge)

autoref Activates the \intro feature (requires the hyperref).
autoref link activates an hyperlink to the target.
autoref target puts a target for a hyperlink.
autorefhere creates an anchor point that points to the \knowledge command
(Requires the hyperref option).
boldface Displays the knowledge in boldface.
color= Displays the knowledge is the given color (resquires xcolor).
colorbox= Displays the knowledge in a box of the given color (requires xcolor).
cyclic color Displays in a color among a cyclic list (requires xcolor).
detokenize Avoids evaluation of the text.
emphasize Emphasizes the displayed output.
ensuretext Guarantees that the output will be displayed in text mode.
ensuremath Guarantees that the output will be displayed in math mode.
export= (not implemented)
invisible= no display
italic= displays in italic
fbox Surround the text with a box.
md Removes boldface typesetting.

**notion**
index= Chooses the text to be displayed in the index=.
index key= the key used to choose the place in the index.
index style= the style to be used to display in the index.
index parent key= the parent key in the index.
intro style= Chooses the typesetting in case of an intro.
italic Typesets the output in italic.
link= Follow with the search the linked knowledge.
link scope= Follow the search in the corresponding scope, using the same key,
or the one provided by link= if present.

**lowercase** Put all letters of the output in lowercase.
mathord, mathop, mathbin, mathrel, mathopen, mathclose, mathpunct Selects a
spacing behaviour in math mode.

**protect link** Disables the hyperlinks inside the link.
ref= Links to a label inside the document.
scope= Choose the scope of the definition.
smallcaps Forces the use of small capitals.
style= Links to a style.
synonym Is a synonym of the lastly defined knowledge.
text= Changes the output text.
remove space removes the spaces from the input
typewriter Typeset in as with \texttt.
underline Underlines the text.
up Removes italic typesetting.
uppercase Put all letters of the output in uppercase.
url= An url to point to (uses the hyperref).
wrap= A macro used to process the displayed text.

### 5.4 List of configuration directives (to use with `\knowledgeconfigure`)

**diagnose bar**={true,false} activates the ‘|’-notation in the diagnose file (default
is false)

**composition** switches to composition mode,
**cyclic colors**= fixes the cyclic list of colors used by the directive cyclic color.
**diagnose line**={true,false} activates or deactivates the line numbering in the
diagnose file.
**electronic** switches to electronic mode,
**fix hyperref twocolumn** fixes a known problem between hyperref and the two
column mode.
**hyperlinks**={true,false} activates or deactivates the hyperlinks.
**notion** activates the notion directive
**paper** switches to paper mode,
\texttt{label scope=\{true,false\}} enables or disables the redefined \texttt{\label} command, which helps automatically define scopes (default is true).

\texttt{protect link} and \texttt{unprotect link} starts and ends respectively a zone in which the \texttt{knowledge} package does not create hyperlinks.

\texttt{protect quotation=\{environment list\}} declares a list of environment in which the\texttt{ quotation notation} should be deactivated

\texttt{quotation=\{true,false\}} activates or deactivates the \texttt{quotation notation}.

\texttt{strict} is a Boolean which, when true, makes the compilation more restrictive by turning some of the warnings into errors (in particular in case of redefinition of knowledges).

\texttt{visible anchor points=\{true,false\}} makes the anchor points either visible or invisible
