

Maximum likelihood estimation and analysis with the **bbmle** package

Ben Bolker

July 29, 2007

The **bbmle** package, designed to simplify maximum likelihood estimation and analysis in R, extends and modifies the **mle** function and class in the **stats4** package that comes with R by default. **mle** is in turn a wrapper around the **optim** function in base R. The maximum-likelihood-estimation function and class in **bbmle** are both called **mle2**, to avoid confusion and conflict with the original functions in the **stats4** package. The major differences between **mle** and **mle2** are:

- **mle2** is slightly more robust, with additional warnings (e.g. if the Hessian can't be computed by finite differences, **mle2** returns a fit with a missing Hessian rather than stopping with an error)
- **mle2** uses a **data** argument to allow different data to be passed to the negative log-likelihood function
- **mle2** has a formula interface like that of (e.g.) **gls** in the **nlme** package. For relatively simple models the formula for the maximum likelihood can be written in-line, rather than defining a negative log-likelihood function. The formula interface also simplifies fitting models with categorical variables.
- **bbmle** defines **anova**, **AIC**, **AICc**, and **BIC** methods for **mle2** objects, as well as **AICtab**, **BICtab**, **AICctab** functions for producing summary tables of information criteria for a set of models.

Other packages with similar functionality (extending GLMs in various ways) are **aod** and **vgam** (on CRAN), **gnlr** and **gnlr3** in Jim Lindsey's **gnlm** package (<http://popgen.unimaas.nl/~jlindsey/rcode.html>).

1 Example

This example will use the classic data set on *Orobanch* germination from [1] (you can also use `glm(...,family="quasibinomial")` or the **aod** package to analyze these data).

1.1 Test basic fit to simulated beta-binomial data

First, generate a single beta-binomially distributed set of points as a simple test.

Load the `emdbook` package to get functions for the beta-binomial distribution (density and random-deviate function — these functions are also available in Jim Lindsey's `rmutil` package).

```
> library(emdbook)
```

Generate random deviates from a random beta-binomial:

```
> set.seed(1001)
> x1 = rbetabinom(n = 1000, prob = 0.1, size = 50, theta = 10)
```

Load the package:

```
> library(bbmle)
```

Construct a simple negative log-likelihood function:

```
> mtmp <- function(prob, size, theta) {
+   -sum(dbetabinom(x1, prob, size, theta, log = TRUE))
+ }
```

Fit the model — use `data` to pass the `size` parameter (since it wasn't hard-coded in the `mtmp` function):

```
> m0 <- mle2(mtmp, start = list(prob = 0.2, theta = 9),
+   data = list(size = 50))
> m0
```

Call:

```
mle2(minuslogl = mtmp, start = list(prob = 0.2, theta = 9), data = list(size = 50))
```

Coefficients:

prob	theta
0.1030974	10.0758090

Log-likelihood: -2723.5

The `summary` method for `mle2` objects shows the parameters; approximate standard errors (based on quadratic approximation to the curvature at the maximum likelihood estimate); and a test of the parameter difference from zero based on this standard error and on an assumption of normality.

```
> summary(m0)
```

Maximum likelihood estimation

Call:

```
mle2(minuslogl = mtmp, start = list(prob = 0.2, theta = 9), data = list(size = 50))
```

Coefficients:

	Estimate	Std. Error	z value	Pr(z)
prob	0.1030974	0.0031624	32.601	< 2.2e-16 ***
theta	10.0758090	0.6213189	16.217	< 2.2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

-2 log L: 5446.995

Construct the likelihood profile (you can apply `confint` directly to `m0`, but if you're going to work with the likelihood profile (e.g. plotting, or looking for confidence intervals at several different α values) then it is more efficient to compute the profile once):

```
> p0 <- profile(m0)
```

Compare the confidence interval estimates based on inverting a spline fit to the profile (the default); based on the quadratic approximation at the maximum likelihood estimate; and based on root-finding to find the exact point where the profile crosses the critical level.

```
> confint(p0)
```

	2.5 %	97.5 %
prob	0.09709228	0.1095103
theta	8.91708211	11.3559591

```
> confint(m0, method = "quad")
```

	2.5 %	97.5 %
prob	0.09689929	0.1092955
theta	8.85804640	11.2935716

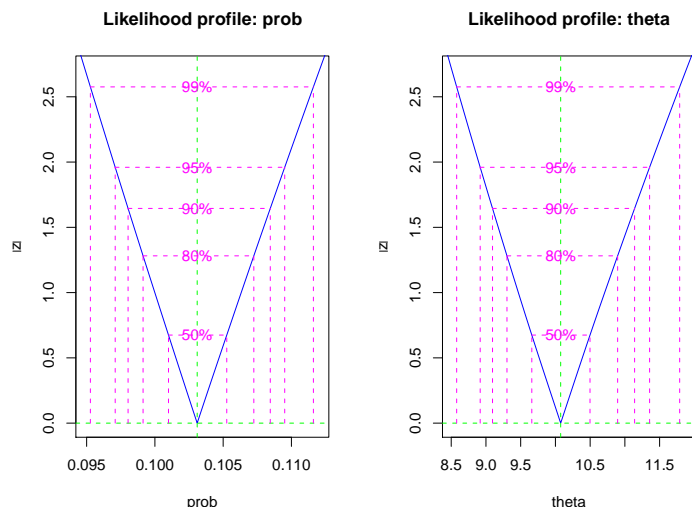

```
> confint(m0, method = "uniroot")
```

	2.5 %	97.5 %
prob	0.09709185	0.1095099
theta	8.91691019	11.3559746

All three types of confidence limits are similar.

Plot the profiles:

```
> par(mfrow = c(1, 2))
> plot(p0, plot.confstr = TRUE)
```

By default, the plot method for likelihood profiles displays the square root of the the deviance (twice the difference in negative log-likelihood), so it will be V-shaped for cases where the quadratic approximation works well (as in this case). (For a better visual estimate of whether the profile is quadratic, use `absVal=FALSE`.)

You can also request confidence intervals calculated using `uniroot`, which may be more exact when the profile is not smooth enough to be modeled accurately by a spline. However, this method is also more sensitive to numeric problems.

Instead of defining an explicit function for `minuslogl`, we can also use the formula interface. The formula interface assumes that the density function given (1) has `x` as its first argument (if the distribution is multivariate, then `x` should be a matrix of observations) and (2) has a `log` argument that will return the log-probability or log-probability density if `log=TRUE`.

```
> m0f <- mle2(x1 ~ dbetabinom(prob, size = 50, theta),
+   start = list(prob = 0.2, theta = 9))
```

It's convenient to use the formula interface to try out likelihood estimation on the transformed parameters:

```
> m0cf <- mle2(x1 ~ dbetabinom(prob = plogis(lprob), size = 50,
+   theta = exp(ltheta)), start = list(lprob = 0, ltheta = 2))
> confint(m0cf, method = "uniroot")
```

```
          2.5 %    97.5 %
lprob -2.229963 -2.095757
ltheta  2.187950  2.429744
```

```
> confint(m0cf, method = "spline")
```

```

          2.5 %    97.5 %
lprob  -2.229963 -2.095756
ltheta  2.187948  2.429742

```

In this case the answers from `uniroot` and `spline` (default) methods barely differ.

1.2 Using real data

Get data from Crowder 1978 [1], as incorporated in the `aod` package:

```
> library(aod)
```

```
Package aod, version 1.1-22
```

```
> data(orob1)
```

Now construct a negative log-likelihood function that differentiates among groups:

```

> ML1 <- function(prob1, prob2, prob3, theta, x) {
+   prob <- c(prob1, prob2, prob3)[as.numeric(x$dilution)]
+   size <- x$n
+   -sum(dbetabinom(x$y, prob, size, theta, log = TRUE))
+ }

```

Results from [1]:

model	prob1	prob2	prob3	theta	sd.prob1	sd.prob2	sd.prob3	NLL
prop diffs	0.132	0.871	0.839	78.424	0.027	0.028	0.032	-34.991
full model								-34.829
homog model								-56.258

```

> m1 <- mle2(ML1, start = list(prob1 = 0.5, prob2 = 0.5,
+   prob3 = 0.5, theta = 1), data = list(x = orob1))
> m1

```

Call:

```
mle2(minuslogl = ML1, start = list(prob1 = 0.5, prob2 = 0.5,
  prob3 = 0.5, theta = 1), data = list(x = orob1))
```

Coefficients:

```

      prob1      prob2      prob3      theta
0.1318287  0.8706204  0.8382700  73.6958477

```

Log-likelihood: -34.99

Warning: optimization did not converge (code 1)

The result warns us that the optimization has not converged; we also don't match Crowder's results for θ exactly. We can fix this by setting `parscale` appropriately.

```
> m2 <- mle2(ML1, start = as.list(coef(m1)), control = list(parscale = coef(m1)),
+           data = list(x = orob1))
```

```
> m2
```

Call:

```
mle2(minuslogl = ML1, start = as.list(coef(m1)), data = list(x = orob1),
     control = list(parscale = coef(m1)))
```

Coefficients:

prob1	prob2	prob3	theta
0.1322123	0.8708914	0.8393195	78.4227872

Log-likelihood: -34.99

Calculate likelihood profile:

```
> p2 <- profile(m2)
```

Get the curvature-based parameter standard deviations (which Crowder used rather than computing likelihood profiles):

```
> round(sqrt(diag(vcov(m2))), 3)
```

prob1	prob2	prob3	theta
0.028	0.029	0.032	74.238

We are slightly off Crowder's numbers — rounding error?

Crowder also defines a variance (overdispersion) parameter $\sigma^2 = 1/(1 + \theta)$.

```
> sqrt(1/(1 + coef(m2)["theta"]))
```

theta
0.1122089

Using the delta method to get the standard deviation of σ :

```
> sqrt(deltavar(sqrt(1/(1 + theta)), meanval = coef(m2)["theta"],
+           vars = "theta", Sigma = vcov(m2)[4, 4]))
```

```
[1] 0.05244163
```

Another way to fit in terms of σ rather than θ is to compute $\theta = 1/\sigma^2 - 1$ on the fly in a formula:

```

> m2b <- mle2(y ~ dbetabinom(prob, size = n, theta = 1/sigma^2 -
+   1), data = orob1, parameters = list(prob ~ dilution,
+   sigma ~ 1), start = list(prob = 0.5, sigma = 0.1))
> round(sqrt(diag(vcov(m2b))), 3)["sigma"]

sigma
0.052

> p2b <- profile(m2b)

As might be expected since the standard deviation of  $\sigma$  is large, the quadratic
approximation is poor:

> r1 <- rbind(confint(p2)["theta", ], confint(m2, method = "quad")["theta",
+   ])
> rownames(r1) <- c("spline", "quad")
> r1

```

	2.5 %	97.5 %
spline	19.81826	NA
quad	-67.08021	223.9258

Plot the profile:

```

> plot(p2, which = "theta", plot.confstr = TRUE)

```

What does the profile for σ look like?

```
> plot(p2b, which = "sigma", plot.confstr = TRUE, show.points = TRUE)
```

Now fit a homogeneous model:

```
> m10 <- function(prob, theta, x) {
+   size <- x$n
+   -sum(dbetabinom(x$y, prob, size, theta, log = TRUE))
+ }
> m0 <- mle2(m10, start = list(prob = 0.5, theta = 100),
+   data = list(x = orob1))
```

The log-likelihood matches Crowder's result:

```
> logLik(m0)

'log Lik.' -56.25774 (df=2)
```

It's easier to use the formula interface to specify all three of the models fitted by Crowder (homogeneous, probabilities differing by group, probabilities and overdispersion differing by group):

```
> m0f <- mle2(y ~ dbetabinom(prob, size = n, theta), parameters = list(prob ~
+   1, theta ~ 1), data = orob1, start = list(prob = 0.5,
+   theta = 100))
> m2f <- mle2(y ~ dbetabinom(prob, size = n, theta), parameters = list(prob ~
```

```

+     dilution, theta ~ 1), data = orob1, start = list(prob = 0.5,
+     theta = 78.424))
> m3f <- mle2(y ~ dbetabinom(prob, size = n, theta), parameters = list(prob ~
+     dilution, theta ~ dilution), data = orob1, start = list(prob = 0.5,
+     theta = 78.424))

```

anova runs a likelihood ratio test on nested models:

```
> anova(m0f, m2f, m3f)
```

Likelihood Ratio Tests

Model 1: m0f, y~dbetabinom(prob,size=n,theta): prob~1, theta~1

Model 2: m2f, y~dbetabinom(prob,size=n,theta): prob~dilution, theta~1

Model 3: m3f, y~dbetabinom(prob,size=n,theta): prob~dilution,
theta~dilution

	Tot	Df	Deviance	Chisq	Df	Pr(>Chisq)
1	2	112.515				
2	4	69.981	42.5341	2	5.805e-10	***
3	6	69.981	0.0008	2	0.9996	

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

The various ICTab commands produce tables of information criteria, optionally sorted and with model weights.

```
> AICtab(m0f, m2f, m3f, weights = TRUE, delta = TRUE, sort = TRUE)
```

	AIC	df	dAIC	weight
m2f	78.0	4	0.0	0.881
m3f	82.0	6	4.0	0.119
m0f	116.5	2	38.5	<0.001

```
> BICtab(m0f, m2f, m3f, delta = TRUE, nobs = nrow(orob1),
+     sort = TRUE, weights = TRUE)
```

	BIC	df	dBIC	weight
m2f	81.1	4	0.0	0.941
m3f	86.6	6	5.5	0.059
m0f	118.1	2	37.0	<0.001

```
> AICctab(m0f, m2f, m3f, delta = TRUE, nobs = nrow(orob1),
+     sort = TRUE, weights = TRUE)
```

	AICc	df	dAICc	weight
m2f	81.6	4	0.0	0.992
m3f	91.3	6	9.7	0.008
m0f	117.4	2	35.8	<0.001

Additions/enhancements/differences from stats4::mle

- anova method
- warnings on convergence failure
- more robust to non-positive-definite Hessian; can also specify `skip.hessian` to skip Hessian computation when it is problematic
- when profiling fails because better value is found, report new values
- can take named vectors as well as lists as starting parameter vectors
- added AICc, BIC definitions, ICtab functions
- added "uniroot" and "quad" options to `confint`
- more options for colors and line types etc etc. The old arguments are:

```
> function(x, levels, conf = c(99, 95, 90, 80, 50)/100,
+         nseg = 50, absVal = TRUE, ...) {
+ }
```

The new one is:

```
> function(x, levels, which = 1:p, conf = c(99, 95, 90,
+      80, 50)/100, nseg = 50, plot.confstr = FALSE, confstr = NULL,
+      absVal = TRUE, add = FALSE, col.minval = "green",
+      lty.minval = 2, col.conf = "magenta", lty.conf = 2,
+      col.prof = "blue", lty.prof = 1, xlab = nm, ylab = "score",
+      show.points = FALSE, main, xlim, ylim, ...) {
+ }
```

`which` selects (by character vector or numbers) which parameters to plot; `nseg` does nothing (even in the old version); `plot.confstr` turns on the labels for the confidence levels; `confstr` gives the labels; `add` specifies whether to add the profile to an existing plot; `col` and `lty` options specify the colors and line types for horizontal and vertical lines marking the minimum and confidence vals and the profile curve; `xlab` gives a vector of x labels; `ylab` gives the y label; `show.points` specifies whether to show the raw points computed.

- `mle.options()`
- `data` argument
- handling of names in argument lists
- can use alternative optimizers (`nlminb`, `constrOptim`)

Bugs, wishes, to do

- **BUG:** `mle2` fits that are obtained within a function can't be used for subsequent profiles etc. (environment issue)
- **WISH:** `subset` and `predict`
- minor **WISH:** better methods for extracting `nobs` information when possible (e.g. with formula interface)
- **WISH:** better documentation, especially for S4 methods
- **WISH:** variable-length chunks in argument list
- **WISH:** limited automatic differentiation (add capability for common distributions)
