dom walk through projections of the data is shown. The user can manipulate the plot to use spec-

Description An HTML widget that randomly tours 2D projections of numerical data. A ran-

ified axes, or turn on Guided Tour mode to find an informative projec-

**Title** Langevin Tour **Version** 0.8.0

tion of the data. Groups within the data can be hidden or shown, as can particular axes. Points can be brushed, and the selection can be linked to other widgets using crosstalk. The underlying method to produce the random walk and projection pursuit uses Langevin dynamics. The widget can be used from within R, or included in a self-contained R Markdown or Quarto document or presentation, or used in a Shiny app.

2 knnDenoise

Index 8

knnDenoise k-nearest neighbor denoising of a set of points	knnDenoise	k-nearest neighbor denoising of a set of points	
--	------------	---	--

# Description

Reduce noise in a high-dimensional dataset by averaging each point with its nearby neighbors.

## Usage

```
knnDenoise(X, block = rep(1, nrow(X)), k = 30, steps = 2)
```

#### **Arguments**

X	A matrix of numeric data, or something that can be cast to a matrix. Each row represents a point.
block	Optional. A block for each row in $X$ . A factor, or something that can be cast to a factor. Denoising will be performed independently within each block.
k	Number of nearest neighbors to find around each point (including itself).
steps	Number of steps to take along the directed k-nearest neighbor graph. steps=1 uses the k-nearest neighbors, steps=2 uses the k-nearest neighbors and their k-nearest neighbors, etc.

### **Details**

knnDenoise first finds the k-nearest neighbors to each point (including the point itself). Then, for each point, the average is found of the points reachable in steps steps along the directed k-nearest neighbor graph.

# **Examples**

```
library(palmerpenguins)

completePenguins <- na.omit(penguins[,c(1,3,4,5,6)])

# Dimensions need to be on comparable scales to apply knnDenoise scaled <- scale(completePenguins[,-1])

denoised <- knnDenoise(scaled)

langevitour(denoised, completePenguins$species, pointSize=2)</pre>
```

langevitour 3

langevitour

Langevin Tour

# Description

Make a Langevin Tour HTML widget, which can be used to explore high-dimensional numerical datasets.

# Usage

```
langevitour(
 Χ,
 group = NULL,
 name = NULL,
 center = NULL,
  scale = NULL,
 extraAxes = NULL,
 lineFrom = NULL,
 lineTo = NULL,
 lineColors = NULL,
 axisColors = NULL,
 levelColors = NULL,
  colorVariation = 0.1,
  pointSize = 1,
  subsample = NULL,
  state = NULL,
 width = NULL,
 height = NULL,
  elementId = NULL,
  link = NULL,
  linkFilter = TRUE,
  enableControls = TRUE
)
```

## **Arguments**

X	The data to plot. A matrix of numeric data, or something that can be cast to a matrix. Rows will be shown as points in the widget. Columns are the variables of your data.
group	A group for each row in X, will be used to color points. A factor, or something that can be cast to a factor.
name	A name for each row in X.
center	Center for each variable. If omitted, the column means will be used.
scale	Scale for each variable (or a single value to apply to all variables). center +/-scale will be the range of guaranteed visible data. If omitted, a reasonable default will be chosen, equal for all variables. (The default is the largest singular value of the centered X times 2.5.)

4 langevitour

extraAxes A matrix with each column defining a projection of interest. The columns of X

%\*% extraAxes will be presented as extra "variables".

lineFrom A vector of row numbers. Draw lines starting at these rows.lineTo A vector of row numbers. Draw lines ending at these rows.

lineColors Character vector. A CSS color for each line.

axisColors Character vector. CSS colors for each variable and then each extra axis.

levelColors Character vector. CSS colors for each level of group.

colorVariation Number between 0 and 1. Individual points are given slightly different bright-

nesses. How strong should this effect be?

pointSize Point radius in pixels. A single number, or a number for each row in X.

subsample For speed, randomly subsample down to this many rows.

state A JSON string, or an object that htmlwidgets will convert to the correct JSON.

Initial widget state settings. The state of a widget can be obtained from its "further controls and information" pane. I am not going to guarantee that states will be compatible between versions of langevitour. Hint: Since JSON uses

double quotes, surround the string in single quotes.

width Width of widget in CSS units, for example "700px" or "100%".

height Height of widget in CSS units, for example "600px" or "75vh".

elementId An element ID for the widget, see htmlwidgets::createWidget.

link A SharedData object from the crosstalk package to share selections and filters

with other htmlwidgets. The data in this object is not used, just the keys and group name. The rows of link\$origData() should correspond to the rows of

X.

linkFilter TRUE or FALSE. If using crosstalk, should hiding groups in langevitour also

cause them to be filtered in linked widgets?

enableControls TRUE or FALSE. If FALSE, all controls and interaction are disabled.

### **Details**

The only required argument is X, the high-dimensional collection of points. The group argument is also commonly used so that groups of points can be distinguished by color. Further arguments adjust the appearance or provide advanced features.

langevitour will by default not scale variables individually. If you want variables to be individually scaled, use something like scale=apply(X,2,sd)\*4. Using the scale argument rather than modifying X directly ensures the plot axes within the widgets retain the original units.

In Javascript, the langevitour object can be obtained using document.getElementById(elementId).langevitour.
For example you could have a button that sets the state of a widget using document.getElementById(elementId).langevi

#### Value

An htmlwidget object.

langevitour-shiny 5

### **Examples**

```
library(palmerpenguins)
completePenguins <- na.omit(penguins[,c(1,3,4,5,6)])</pre>
scale <- apply(completePenguins[,-1], 2, sd)*4</pre>
langevitour(
   completePenguins[,-1],
    completePenguins$species,
    scale=scale, pointSize=2)
# An example setting the widget's initial state
langevitour(
    completePenguins[,-1],
    completePenguins$species,
    scale=scale, pointSize=2,
    state='{"guideType":"pca","labelInactive":["bill_length_mm"]}')
# An example with controls and interaction disabled
langevitour(
    completePenguins[,-1],
    completePenguins$species,
    scale=scale, pointSize=2,
    enableControls=FALSE)
```

langevitour-shiny

Shiny bindings for langevitour

## **Description**

Output and render functions for using langevitour within Shiny applications and interactive Rmd documents.

## Usage

```
langevitourOutput(outputId, width = "100%", height = "600px")
renderLangevitour(expr, env = parent.frame(), quoted = FALSE)
```

#### **Arguments**

outputId output variable to read from

width, height Must be a valid CSS unit (like '100%', '400px', 'auto') or a number, which

will be coerced to a string and have 'px' appended.

6 zeiselPC

expr An expression that generates a langevitour, usually a block of code ending with

a call to langevitour()

env The environment in which to evaluate expr.

quoted Is expr a quoted expression (with quote())? This is useful if you want to save

an expression in a variable.

## **Examples**

```
library(shiny)
library(palmerpenguins)
completePenguins <- na.omit(penguins[,c(1,3,4,5,6)])</pre>
scale <- apply(completePenguins[,-1], 2, sd)*4</pre>
ui <- fluidPage(</pre>
    sliderInput('zoom', 'Zoom', 0, min=-1, max=1, step=0.1),
    langevitourOutput('widget')
)
server <- function(input,output) {</pre>
    output$widget <- renderLangevitour({</pre>
        langevitour(
             completePenguins[,-1],
             completePenguins$species,
             scale=scale * 10^input$zoom, pointSize=2)
    })
app <- shinyApp(ui, server)</pre>
# Use runApp(app) or runGadget(app) to run app.
```

zeiselPC

Principal components of scRNA-Seq of mouse brain cells

## **Description**

Single-cell RNA-Seq gene expression of 2,816 mouse brain cells (Zeisel, 2015). The top 10 principal components were produced using the steps in the Bioconductor OSCA workflow.

#### Usage

```
data(zeiselPC)
```

zeiselPC 7

#### **Format**

A data frame with 2,816 rows representing brain cells and 11 columns:

type Cell type.

PC1 Principal component score.

PC2 Principal component score.

PC3 Principal component score.

**PC4** Principal component score.

PC5 Principal component score.

PC6 Principal component score.

PC7 Principal component score.

PC8 Principal component score.

PC9 Principal component score.

PC10 Principal component score.
