

Package ‘netmeta’

April 10, 2025

Title Network Meta-Analysis using Frequentist Methods

Version 3.2-0

Date 2025-04-10

Depends R (>= 4.0.0), meta (>= 8.0-1)

Imports Matrix, metafor, MASS, mvtnorm, magic, igraph, ggplot2, colorspace, grid, dplyr, magrittr, methods

Suggests Rgraphviz, graph, rgl, gridExtra, tictoc, writexl, R.rsp, cccp, brglm2, crossnma

URL <https://github.com/guido-s/netmeta>

Description A comprehensive set of functions providing frequentist methods for network meta-analysis (Balduzzi et al., 2023) <[doi:10.18637/jss.v106.i02](https://doi.org/10.18637/jss.v106.i02)> and supporting Schwarzer et al. (2015) <[doi:10.1007/978-3-319-21416-0](https://doi.org/10.1007/978-3-319-21416-0)>, Chapter 8 “Network Meta-Analysis”:

- frequentist network meta-analysis following Rücker (2012) <[doi:10.1002/jrsm.1058](https://doi.org/10.1002/jrsm.1058)>;
- additive network meta-analysis for combinations of treatments (Rücker et al., 2020) <[doi:10.1002/bimj.201800167](https://doi.org/10.1002/bimj.201800167)>;
- network meta-analysis of binary data using the Mantel-Haenszel or non-central hypergeometric distribution method (Efthimiou et al., 2019) <[doi:10.1002/sim.8158](https://doi.org/10.1002/sim.8158)>, or penalised logistic regression (Evrenoglou et al., 2022) <[doi:10.1002/sim.9562](https://doi.org/10.1002/sim.9562)>;
- rankograms and ranking of treatments by the Surface under the cumulative ranking curve (SU-CRA) (Salanti et al., 2013) <[doi:10.1016/j.jclinepi.2010.03.016](https://doi.org/10.1016/j.jclinepi.2010.03.016)>;
- ranking of treatments using P-scores (frequentist analogue of SUCRAs without resampling) according to Rücker & Schwarzer (2015) <[doi:10.1186/s12874-015-0060-8](https://doi.org/10.1186/s12874-015-0060-8)>;
- split direct and indirect evidence to check consistency (Dias et al., 2010) <[doi:10.1002/sim.3767](https://doi.org/10.1002/sim.3767)>, (Efthimiou et al., 2019) <[doi:10.1002/sim.8158](https://doi.org/10.1002/sim.8158)>;
- league table with network meta-analysis results;
- 'comparison-adjusted' funnel plot (Chaimani & Salanti, 2012) <[doi:10.1002/jrsm.57](https://doi.org/10.1002/jrsm.57)>;
- net heat plot and design-based decomposition of Cochran's Q according to Krahn et al. (2013) <[doi:10.1186/1471-2288-13-35](https://doi.org/10.1186/1471-2288-13-35)>;
- measures characterizing the flow of evidence between two treatments by König et al. (2013) <[doi:10.1002/sim.6001](https://doi.org/10.1002/sim.6001)>;
- automated drawing of network graphs described in Rücker & Schwarzer (2016) <[doi:10.1002/jrsm.1143](https://doi.org/10.1002/jrsm.1143)>;

- partial order of treatment rankings ('poset') and Hasse diagram for 'poset' (Carlsen & Bruggemann, 2014) <doi:10.1002/cem.2569>; (Rücker & Schwarzer, 2017) <doi:10.1002/jrsm.1270>;
- contribution matrix as described in Papakonstantinou et al. (2018) <doi:10.12688/f1000research.14770.3> and Davies et al. (2022) <doi:10.1002/sim.9346>;
- network meta-regression with a single continuous or binary covariate;
- subgroup network meta-analysis.

netmeta-package	<i>netmeta: Brief overview of methods and general hints</i>
-----------------	---

Description

R package **netmeta** (Balduzzi et al., 2023) provides frequentist methods for network meta-analysis and supports Schwarzer et al. (2015), Chapter 8 on network meta-analysis <https://link.springer.com/book/10.1007/978-3-319-21416-0>.

Details

R package **netmeta** is an add-on package for **meta** providing the following network meta-analysis models:

- frequentist network meta-analysis (function `netmeta`) based on Rucker (2012) and Rucker & Schwarzer (2014);
- additive network meta-analysis for combinations of treatments (`netcomb` for connected networks, `discomb` for disconnected networks) (Rucker et al., 2020a);
- network meta-analysis of binary data (`netmetabin`) using the Mantel-Haenszel or non-central hypergeometric distribution method (Efthimiou et al., 2019), or penalised logistic regression (Evrenoglou et al., 2022).

The following methods are available to present results of a network meta-analysis:

- network graphs (`netgraph`) described in Rucker & Schwarzer (2016);
- forest plots (`forest.netmeta`, `forest.netcomb`);

- league tables with network meta-analysis results ([netleague](#));
- tables with network, direct and indirect estimates ([nettable](#)) looking similar to the statistical part of a GRADE table for a network meta-analysis (Puhan et al., 2014).

The following methods are implemented to rank treatments:

- rankograms ([rankogram](#)) (Salanti et al., 2011);
- ranking of treatments ([netrank](#)) based on P-scores (Rücker & Schwarzer, 2015) or the Surface Under the Cumulative RAnking curve (SUCRA) (Salanti et al., 2011);
- partial order of treatment rankings ([netposet](#), [plot.netposet](#)) and Hasse diagram ([hasse](#)) according to Carlsen & Bruggemann (2014) and Rücker & Schwarzer (2017).

Available functions to evaluate network inconsistency:

- split direct and indirect evidence ([netsplit](#)) to check for consistency (Dias et al., 2010; Efthimiou et al., 2019);
- net heat plot ([netheat](#)) and design-based decomposition of Cochran's Q ([decomp.design](#)) described in Krahn et al. (2013).

Additional methods and functions:

- network meta-regression with a single continuous or binary covariate ([netmetareg](#));
- subgroup network meta-analysis ([subgroup.netmeta](#));
- information on network connectivity ([netconnection](#));
- contribution of direct comparisons to network estimates ([netcontrib](#)) (Papakonstantinou et al., 2018; Davies et al., 2022);
- importance of individual studies measured by reduction of precision if removed from network ([netimpact](#)) (Rücker et al., 2020b);
- 'comparison-adjusted' funnel plot ([funnel.netmeta](#)) to assess funnel plot asymmetry in network meta-analysis (Chaimani & Salanti, 2012);
- conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis ([netpairwise](#));
- results of several network meta-analyses can be combined with [netbind](#) to show these results in a forest plot ([forest.netbind](#)).
- measures characterizing the flow of evidence between two treatments ([netmeasures](#)) described in König et al. (2013);
- calculate comparison effects of two arbitrary complex interventions in component network meta-analysis ([netcomparison](#));
- calculate effect of arbitrary complex interventions in component network meta-analysis ([netcomplex](#)).

Functions and datasets from **netmeta** are utilised in Schwarzer et al. (2015), Chapter 8 "Network Meta-Analysis", <https://link.springer.com/book/10.1007/978-3-319-21416-0>.

Type `help(package = "netmeta")` for a listing of all R functions available in **netmeta**.

Type `citation("netmeta")` on how to cite **netmeta** in publications.

To report problems and bugs

- type `bug.report(package = "netmeta")` if you do not use RStudio,
- send an email to Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de> if you use RStudio.

The development version of **netmeta** is available on GitHub <https://github.com/guido-s/netmeta>.

as.data.frame.netconnection

Create a data frame from an object of class netconnection

Description

The `as.data.frame` method returns a data frame containing information on membership of studies / pairwise comparisons to a (sub)network.

Usage

```
## S3 method for class 'netconnection'  
as.data.frame(x, ...)
```

Arguments

`x` An object of class `netconnection`.
`...` Additional arguments (ignored).

Value

A data frame is returned by the function `as.data.frame`.

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

See Also[netconnection](#)**Examples**

```
# Artificial example with two subnetworks
#
t1 <- c("G", "B", "B", "D", "A", "F")
t2 <- c("B", "C", "E", "E", "H", "A")
#
nc2 <- netconnection(t1, t2)
print(nc2, details = TRUE)

as.data.frame(nc2)
```

as.data.frame.netmeta *Create a data frame from an object of class netmeta*

Description

The `as.data.frame` method returns a data frame containing information on individual studies, e.g., estimated treatment effect and its standard error.

Usage

```
## S3 method for class 'netmeta'
as.data.frame(x, row.names = NULL, optional = FALSE, details = FALSE, ...)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>row.names</code>	NULL or a character vector giving the row names for the data frame.
<code>optional</code>	A logical. If TRUE, setting row names and converting column names (to syntactic names) is optional.
<code>details</code>	A logical. If TRUE, additional variables of less interest are included in data frame.
<code>...</code>	Additional arguments.

Value

A data frame is returned by the function `as.data.frame`.

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

See Also[netmeta](#)**Examples**

```

data(smokingcessation)

# Transform data from arm-based format to contrast-based format
#
pw1 <- pairwise(list(treat1, treat2, treat3),

  data = smokingcessation, sm = "OR")

# Conduct random effects network meta-analysis and show data frame
#
net1 <- netmeta(pw1, common = FALSE)
head(as.data.frame(net1))
head(as.data.frame(net1, details = TRUE))

```

Baker2009

Network meta-analysis of pharmacologic treatments for chronic obstructive pulmonary disease

Description

This dataset comes from a systematic review of randomized controlled trials on pharmacologic treatments for chronic obstructive pulmonary disease (COPD) (Baker et al., 2009).

The primary outcome, occurrence of one or more episodes of COPD exacerbation, is binary (yes / no). For this outcome, five drug treatments (fluticasone, budesonide, salmeterol, formoterol, tiotropium) and two combinations (fluticasone + salmeterol, budesonide + formoterol) were compared to placebo. The authors considered the two combinations as separate treatments instead of evaluating the individual components.

Format

A data frame with the following columns:

<i>study</i>	study label
<i>year</i>	year of publication
<i>id</i>	study ID
<i>treatment</i>	treatment
<i>exac</i>	one or more episodes of COPD exacerbation
<i>total</i>	number of individuals in treatment arm

Note

The dataset Baker2009 is identical to dataset [dat.baker2009](#) in R package **metadat**.

createC

Auxiliary functions for component network meta-analysis

Description

Auxiliary functions to (i) create a combination / C matrix with information on treatment combinations and interaction terms and (ii) a vector with all combinations in a component network meta-analysis.

Usage

```
createC(x, ...)

## S3 method for class 'matrix'
createC(
  x,
  comb.ia,
  inactive = NULL,
  sep.comps = gs("sep.comps"),
  sep.ia = gs("sep.ia"),
  ...
)

## S3 method for class 'netcomb'
createC(x, comb.ia = NULL, inactive = NULL, sep.ia = x$sep.ia, ...)

## S3 method for class 'netmeta'
createC(x, inactive = NULL, sep.comps = gs("sep.comps"), ...)

## S3 method for class 'netconnection'
createC(x, inactive = NULL, sep.comps = gs("sep.comps"), ...)
```

```
## Default S3 method:
createC(x, n = 1, ...)

combinations(x, n = NULL)
```

Arguments

<code>x</code>	A netcomb , netmeta or netconnection object, a matrix or the number of components.
<code>...</code>	Additional arguments.
<code>comb.ia</code>	A character vector specifying treatment combinations which will be considered as interactions.
<code>inactive</code>	A character string defining the inactive treatment component (see netcomb).
<code>sep.comps</code>	A single character to define separator between treatment components.
<code>sep.ia</code>	A single character to define separator for interactions.
<code>n</code>	A single number specifying the number of components in combinations.

Value

R function `createC` returns a combination matrix / C matrix with studies in rows and component and interaction terms in columns.

R function `combinations` returns a character vector with combinations.

```

<code>crossnma2netmeta</code>	<i>Create a netmeta object from a crossnma object</i>
-------------------------------	---

Description

Auxiliary function to create a netmeta object from a crossnma object

Usage

```
crossnma2netmeta(
  x,
  keep.samples = TRUE,
  level = gs("level"),
  level.ma = x$model$level.ma,
  reference.group = x$model$reference,
  baseline.reference = gs("baseline.reference"),
  small.values = x$model$small.values,
  all.treatments = gs("all.treatments"),
  seq = gs("seq"),
  backtransf = x$model$backtransf,
  nchar.trts = gs("nchar.trts"),
  nchar.studlab = gs("nchar.studlab")
)
```

Arguments

<code>x</code>	A crossnma object created with R package crossnma .
<code>keep.samples</code>	A logical indicating whether to keep the generated samples.
<code>level</code>	The level used to calculate confidence intervals for individual comparisons.
<code>level.ma</code>	The level used to calculate confidence intervals for network estimates.
<code>reference.group</code>	Reference treatment (first treatment is used if argument is missing).
<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if <code>reference.group</code> has been specified.
<code>small.values</code>	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect (passed on to netrank , can be abbreviated).
<code>all.treatments</code>	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
<code>seq</code>	A character or numerical vector specifying the sequence of treatments in printouts.
<code>backtransf</code>	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names (see Details).
<code>nchar.studlab</code>	A numeric defining the minimum number of characters used to create unique study labels.

Value

A netmeta object with additional class "netmeta.crossnma".

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

See Also

[netmeta](#)

Examples

```

  rankogram(cro)
}
```

decomp.design

Design-based decomposition of Cochran's Q in network meta-analysis

Description

This function performs a design-based decomposition of Cochran's Q for assessing the homogeneity in the whole network, the homogeneity within designs, and the homogeneity/consistency between designs. It allows also an assessment of the consistency assumption after detaching the effect of single designs.

Usage

```
decomp.design(
  x,
  tau.preset = x$tau.preset,
  warn = gs("warn"),
  nchar.trts = x$nchar.trts
)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>tau.preset</code>	An optional value for the square-root of the between-study variance τ^2 (see <code>Details</code>).
<code>warn</code>	A logical indicating whether warnings should be printed.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.

Details

In the context of network meta-analysis and the assessment of the homogeneity and consistency assumption, a generalized Cochran's Q statistic for multivariate meta-analysis can be used as shown in Krahn et al. (2013). This Q statistic can be decomposed in a sum of within-design Q statistics and one between-designs Q statistic that incorporates the concept of design inconsistency, see Higgins et al. (2012).

For assessing the inconsistency in a random effects model, the between-designs Q statistic can be calculated based on a full design-by-treatment interaction random effects model (see Higgins et al., 2012). This Q statistic will be automatically given in the output (τ^2 estimated by the method of moments (see Jackson et al., 2012)). Alternatively, the square-root of the between-study variance can be prespecified by argument `tau.preset` to obtain a between-designs Q statistic (in `Q.inc.random`), its design-specific contributions `Q.inc.design.random.preset` as well as residuals after detaching of single designs (`residuals.inc.detach.random.preset`).

Since an inconsistent treatment effect of one design can simultaneously inflate several residuals, Krahn et al. (2013) suggest for locating the inconsistency in a network to fit a set of extended models allowing for example for a deviating effect of each study design in turn. The recalculated between-designs Q statistics are given in list component `Q.inc.detach`. The change of the inconsistency contribution of single designs can be investigated in more detail by a net heat plot (see function [netheat](#)). Designs where only one treatment is involved in other designs of the network or where the removal of corresponding studies would lead to a splitting of the network do not contribute to the inconsistency assessment. These designs are not included in `Q.inc.detach`.

Value

Network meta-analysis with a single design: `NULL`. Otherwise, a list containing the following components:

<code>Q.decomp</code>	Data frame with Q statistics (variable <code>Q</code>) based on the common effects model to assess the homogeneity/consistency in the whole network, within designs, and between designs. Corresponding degrees of freedom (<code>df</code>) and p-values (<code>p.val</code>) are also given.
<code>Q.het.design</code>	Data frame with design-specific decomposition of the within-designs Q statistic (<code>Q</code>) of the common effects model, corresponding degrees of freedom (<code>df</code>) and p-values (<code>p.val</code>) are given.
<code>Q.inc.detach</code>	Data frame with between-designs Q statistics (<code>Q</code>) of the common effects model after detaching of single designs, corresponding degrees of freedom (<code>df</code>) and p-values (<code>p.val</code>) are given.

<code>Q.inc.design</code>	A named vector with contributions of single designs to the between design Q statistic given in <code>Q.decomp</code> .
<code>Q.inc.random</code>	Data frame with between-designs Q statistic (Q) based on a random effects model with square-root of between-study variance <code>tau.within</code> estimated embedded in a full design-by-treatment interaction model, corresponding degrees of freedom (df) and p-value (<code>p.val</code>).
<code>Q.inc.random.preset</code>	Data frame with between-designs Q statistic (Q) based on a random effects model with prespecified square-root of between-study variance <code>tau.preset</code> in the case if argument <code>tau.preset</code> is not NULL, corresponding degrees of freedom (df) and p-value (<code>p.val</code>).
<code>Q.inc.design.random.preset</code>	A named vector with contributions of single designs to the between design Q statistic based on a random effects model with prespecified square-root of between-study variance <code>tau.preset</code> in the case if argument <code>tau.preset</code> is given.
<code>residuals.inc.detach</code>	Matrix with residuals, i.e. design-specific direct estimates minus the corresponding network estimates after detaching the design of the column.
<code>residuals.inc.detach.random.preset</code>	Matrix with residuals analogous to <code>residuals.inc.detach</code> but based on a random effects model with prespecified square-root of between-study variance <code>tau.preset</code> in the case if argument <code>tau.preset</code> is not NULL.
<code>call</code>	Function call.
<code>version</code>	Version of R package <code>netmeta</code> used to create object.

dietaryfat

Network meta-analysis of dietary fat

Description

Network meta-analysis comparing the effects of two diets to control on mortality.

The data are rates, given as the number of deaths and person-years. These data are used as an example in the supplemental material of Dias et al. (2013).

Format

A data frame with the following columns:

<i>treat1</i>	treatment 1
<i>treat2</i>	treatment 2
<i>treat3</i>	treatment 3
<i>years1</i>	person years arm 1
<i>years2</i>	person years arm 2
<i>years3</i>	person years arm 3
<i>d1</i>	events (deaths) arm 1
<i>d2</i>	events (deaths) arm 2
<i>d3</i>	events (deaths) arm 3
<i>ID</i>	study ID

discomb	<i>Additive network meta-analysis for combinations of treatments (disconnected networks)</i>
---------	--

Description

Some treatments in a network meta-analysis may be combinations of other treatments or have common components. The influence of individual components can be evaluated in an additive network meta-analysis model assuming that the effect of treatment combinations is the sum of the effects of its components. This function implements this additive model in a frequentist way and is particularly intended for disconnected networks.

Usage

```
discomb(
  TE,
  seTE,
  treat1,
  treat2,
  studlab,
  data = NULL,
  subset = NULL,
  inactive = NULL,
  sep.comps = gs("sep.comps"),
  C.matrix,
  sm,
  level = gs("level"),
  level.ma = gs("level.ma"),
  common = gs("common"),
  random = gs("random") | !is.null(tau.preset),
  reference.group,
  baseline.reference = gs("baseline.reference"),
  seq = gs("sep"),
  tau.preset = NULL,
  tol.multiarm = gs("tol.multiarm"),
  tol.multiarm.se = gs("tol.multiarm.se"),
  details.chkmultiarm = gs("details.chkmultiarm"),
```

```

details.chkident = FALSE,
sep.trts = gs("sep.trts"),
nchar.comps = gs("nchar.comps"),
sep.ia = gs("sep.ia"),
func.inverse = invmat,
n1 = NULL,
n2 = NULL,
event1 = NULL,
event2 = NULL,
incr = NULL,
overall.hetstat = gs("overall.hetstat"),
backtransf = gs("backtransf"),
na.unident = gs("na.unident"),
title = gs("title"),
keepdata = gs("keepdata"),
warn = gs("warn"),
warn.deprecated = gs("warn.deprecated"),
nchar.trts = nchar.comps,
...
)

```

Arguments

TE	Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio, mean difference, or log hazard ratio). Or an R object created with pairwise .
seTE	Standard error of treatment estimate.
treat1	Label/Number for first treatment.
treat2	Label/Number for second treatment.
studlab	An optional - but important! - vector with study labels (see netmeta).
data	An optional data frame containing the study information.
subset	An optional vector specifying a subset of studies to be used.
inactive	A character string defining the inactive treatment component (see Details).
sep.comps	A single character to define separator between treatment components.
C.matrix	C matrix (see Details).
sm	A character string indicating underlying summary measure, e.g., "RD", "RR", "OR", "ASD", "HR", "MD", "SMD", or "ROM".
level	The level used to calculate confidence intervals for individual comparisons.
level.ma	The level used to calculate confidence intervals for network estimates.
common	A logical indicating whether a common effects / common effects network meta-analysis should be conducted.
random	A logical indicating whether a random effects network meta-analysis should be conducted.
reference.group	Reference treatment (first treatment is used if argument is missing).

<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if <code>reference.group</code> has been specified.
<code>seq</code>	A character or numerical vector specifying the sequence of treatments in print-outs.
<code>tau.preset</code>	An optional value for the square-root of the between-study variance τ^2 .
<code>tol.multiarm</code>	A numeric for the tolerance for consistency of treatment estimates in multi-arm studies which are consistent by design.
<code>tol.multiarm.se</code>	A numeric for the tolerance for consistency of standard errors in multi-arm studies which are consistent by design. This check is not conducted if the argument is NULL.
<code>details.chkmultiarm</code>	A logical indicating whether treatment estimates and / or variances of multi-arm studies with inconsistent results or negative multi-arm variances should be printed.
<code>details.chkident</code>	A logical indicating whether details on unidentifiable components should be printed.
<code>sep.trts</code>	A character used in comparison names as separator between treatment labels.
<code>nchar.comps</code>	A numeric defining the minimum number of characters used to create unique names for components (see Details).
<code>sep.ia</code>	A single character to define separator for interactions.
<code>func.inverse</code>	R function used to calculate the pseudoinverse of the Laplacian matrix L (see netmeta).
<code>n1</code>	Number of observations in first treatment group.
<code>n2</code>	Number of observations in second treatment group.
<code>event1</code>	Number of events in first treatment group.
<code>event2</code>	Number of events in second treatment group.
<code>incr</code>	Numerical value added to cell frequencies.
<code>overall.hetstat</code>	A logical indicating whether to print heterogeneity measures.
<code>backtransf</code>	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>na.unident</code>	A logical indicating whether unidentifiable components and combinations should be set to missing values.
<code>title</code>	Title of meta-analysis / systematic review.
<code>keepdata</code>	A logical indicating whether original data(set) should be kept in netmeta object.
<code>warn</code>	A logical indicating whether warnings should be printed (e.g., if studies are excluded from meta-analysis due to zero standard errors).

warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
nchar.trts	Deprecated argument (replaced by nchar.comps).
...	Additional arguments (to catch deprecated arguments).

Details

Treatments in network meta-analysis (NMA) can be complex interventions. Some treatments may be combinations of others or have common components. The standard analysis provided by [netmeta](#) is a NMA where all existing (single or combined) treatments are considered as different nodes in the network. Exploiting the fact that some treatments are combinations of common components, an additive component network meta-analysis (CNMA) model can be used to evaluate the influence of individual components. This model assumes that the effect of a treatment combination is the sum of the effects of its components which implies that common components cancel out in comparisons.

This R function can be used for disconnected networks. Use [netmeta](#) and [netcomb](#) for connected networks.

The additive CNMA model has been implemented using Bayesian methods (Mills et al., 2012; Welton et al., 2013). This function implements the additive model in a frequentist way (Rücker et al., 2020).

The underlying multivariate model is given by

$$\delta = B\theta, \theta = C\beta$$

with

δ vector of true treatment effects (differences) from individual studies,

B design matrix describing the structure of the network,

θ parameter vector that represents the existing combined treatments,

C matrix describing how the treatments are composed,

β parameter vector representing the treatment components.

All parameters are estimated using weighted least squares regression.

Argument `inactive` can be used to specify a single component that does not have any therapeutic value. Accordingly, it is assumed that the treatment effect of the combination of this component with an additional treatment component is equal to the treatment effect of the additional component alone.

Argument `sep.comps` can be used to specify the separator between individual components. By default, the matrix C is calculated internally from treatment names. However, it is possible to specify a different matrix using argument `C.matrix`.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see [abbreviate](#), argument `minlength`). R function [treats](#) is utilised internally to create abbreviated component names.

Value

An object of classes `discomb` and `netcomb` with corresponding `print`, `summary`, and `forest` functions. The object is a list containing the following components:

<code>studlab</code>	Study labels.
<code>treat1</code>	Label/Number for first treatment.
<code>treat2</code>	Label/Number for second treatment.
<code>TE</code>	Estimate of treatment effect, i.e. difference between first and second treatment.
<code>seTE</code>	Standard error of treatment estimate.
<code>seTE.adj.common</code> , <code>seTE.adj.random</code>	Standard error of treatment estimate, adjusted for multi-arm studies.
<code>event1</code>	Number of events in first treatment group.
<code>event2</code>	Number of events in second treatment group.
<code>n1</code>	Number of observations in first treatment group.
<code>n2</code>	Number of observations in second treatment group.
<code>k</code>	Total number of studies.
<code>m</code>	Total number of pairwise comparisons.
<code>n</code>	Total number of treatments.
<code>d</code>	Total number of designs (corresponding to the unique set of treatments compared within studies).
<code>c</code>	Total number of components.
<code>trts</code>	Treatments included in network meta-analysis.
<code>comps</code>	Unique list of components present in the network.
<code>TE.cnma.common</code> , <code>TE.cnma.random</code>	A vector of length m of consistent treatment effects estimated by the additive (common and random effects) model.
<code>seTE.cnma.common</code> , <code>seTE.cnma.random</code>	A vector of length m with standard errors estimated by the additive (common and random effects) model.
<code>lower.cnma.common</code> , <code>lower.cnma.random</code>	A vector of length m of lower confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.
<code>upper.cnma.common</code> , <code>upper.cnma.random</code>	A vector of length m of upper confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.
<code>statistic.cnma.common</code> , <code>statistic.cnma.random</code>	A vector of length m of z-values for the test of an overall effect estimated by the additive (common and random effects) model.
<code>pval.cnma.common</code> , <code>pval.cnma.random</code>	A vector of length m of p-values for the test of an overall effect estimated by the additive (common and random effects) model.

TE.common, TE.random	nxn matrix with overall treatment effects estimated by the additive (common and random effects) model.
seTE.common, seTE.random	nxn matrix with standard errors estimated by the additive (common and random effects) model.
lower.common, upper.common, lower.random, upper.random	nxn matrices with lower and upper confidence interval limits estimated by the additive (common and random effects) model.
statistic.common, pval.common, statistic.random, pval.random	nxn matrices with z-values and p-values for test of overall effect estimated by the additive (common and random effects) model.
Comp.common, Comp.random	A vector of component effects (common and random effects model).
seComp.common, seComp.random	A vector with corresponding standard errors (common and random effects model).
lower.Comp.common, lower.Comp.random	A vector with lower confidence limits for components (common and random effects model).
upper.Comp.common, upper.Comp.random	A vector with upper confidence limits for components (common and random effects model).
statistic.Comp.common, statistic.Comp.random	A vector with z-values for the overall effect of components (common and random effects model).
pval.Comp.common, pval.Comp.random	A vector with p-values for the overall effect of components (common and random effects model).
Comb.common, Comb.random	A vector of combination effects (common and random effects model).
seComb.common, seComb.random	A vector with corresponding standard errors (common and random effects model).
lower.Comb.common, lower.Comb.random	A vector with lower confidence limits for combinations (common and random effects model).
upper.Comb.common, upper.Comb.random	A vector with upper confidence limits for combinations (common and random effects model).
statistic.Comb.common, statistic.Comb.random	A vector with z-values for the overall effect of combinations (common and random effects model).
pval.Comb.common, pval.Comb.random	A vector with p-values for the overall effect of combinations (common and random effects model).
Q.additive	Overall heterogeneity / inconsistency statistic (additive model).
df.Q.additive	Degrees of freedom for test of heterogeneity / inconsistency (additive model).

pval.Q.additive	P-value for test of heterogeneity / inconsistency (additive model).
tau	Square-root of between-study variance (additive model).
I2	I-squared (additive model).
Q.standard	Overall heterogeneity / inconsistency statistic (standard model).
df.Q.standard	Degrees of freedom for test of heterogeneity / inconsistency (standard model).
pval.Q.standard	P-value for test of heterogeneity / inconsistency (standard model).
Q.diff	Test statistic for difference in goodness of fit between standard and additive model.
df.Q.diff	Degrees of freedom for difference in goodness of fit between standard and additive model.
pval.Q.diff	P-value for difference in goodness of fit between standard and additive model.
X.matrix	Design matrix (mxn).
B.matrix	Edge-vertex incidence matrix (mxn).
C.matrix	As defined above.
sm	Summary measure.
level.ma	Level for confidence intervals.
common, random, tau.preset	As defined above.
sep.trts	A character used in comparison names as separator between treatment labels.
nchar.comps	A numeric defining the minimum number of characters used to create unique component names.
inactive, sep.comps	As defined above.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots.
title	Title of meta-analysis / systematic review.
x	As defined above.
call	Function call.
version	Version of R package netmeta used to create object.

Note

This function calculates effects for individual components and complex interventions present in the network.

R function [netcomplex](#) can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis. Furthermore, R function [netcomparison](#) can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

Dogliotti2014

Network meta-analysis of antithrombotic treatments in patients with non-valvular atrial fibrillation

Description

This dataset comes from a systematic review aiming to determine the effects of eight antithrombotic treatments in reducing the incidence of major thrombotic events in patients with non-valvular atrial fibrillation (Dogliotti et al., 2014). The review included 20 studies (79,808 participants), four of which were three-arm studies. The primary outcome is stroke reduction.

Format

A data frame with the following columns:

<i>study</i>	study label
<i>id</i>	study ID
<i>treatment</i>	treatment
<i>stroke</i>	number of strokes
<i>total</i>	number of individuals in treatment arm

Note

The dataset Dogliotti2014 is identical to dataset `dat.dogliotti2014` in R package `metadat`.

Source

Dogliotti A, Paolasso E, Giugliano RP (2014): Current and new oral antithrombotics in non-valvular atrial fibrillation: a network meta-analysis of 79 808 patients. *Heart*, **100**, 396–405

Dong2013

Network meta-analysis for chronic obstructive pulmonary disease

Description

Network meta-analysis comparing inhaled medications in patients with chronic obstructive pulmonary disease.

Format

A data frame with the following columns:

<i>id</i>	study ID
<i>treatment</i>	treatment
<i>death</i>	mortality
<i>randomized</i>	number of individuals in treatment arm

Note

The dataset Dong2013 is identical to dataset [dat.dong2013](#) in R package **metadat**.

forest.netbind

Forest plot showing results of two or more network meta-analyses

Description

Forest plot to show network estimates of two or more network meta-analyses.

Usage

```
## S3 method for class 'netbind'
forest(
  x,
  pooled = ifelse(x$x$random, "random", "common"),
  equal.size = gs("equal.size"),
  leftcols = "studlab",
  leftlabs = "Treatment",
  rightcols = c("effect", "ci"),
  rightlabs = NULL,
  subset.treatments,
  digits = gs("digits.forest"),
  digits.prop = max(gs("digits.pval") - 2, 2),
  backtransf = x$backtransf,
  lab.NA = gs("lab.NA"),
  smlab,
  ...
)

## S3 method for class 'netbind'
plot(x, ...)
```

Arguments

x	An object of class netbind.
pooled	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
equal.size	A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
leftcols	A character vector specifying columns to be plotted on the left side of the forest plot (see Details).
leftlabs	A character vector specifying labels for columns on left side of the forest plot.
rightcols	A character vector specifying columns to be plotted on the right side of the forest plot (see Details).
rightlabs	A character vector specifying labels for columns on right side of the forest plot.
subset.treatments	A character vector specifying treatments to show in forest plot as comparators to the reference.

digits	Minimal number of significant digits for treatment effects and confidence intervals, see <code>print.default</code> .
digits.prop	Minimal number of significant digits for the direct evidence proportion.
backtransf	A logical indicating whether results should be back transformed in forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
lab.NA	A character string to label missing values.
smlab	A label printed at top of figure. By default, text indicating either common or random effects model is printed.
...	Additional arguments for <code>forest.meta</code> function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window.

The arguments `leftcols` and `rightcols` can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. If argument `rightcols` is `FALSE`, no columns will be plotted on the right side.

For more information see help page of `forest.meta` function.

```

forest.netcomb

Forest plot for additive network meta-analysis

Description

Draws a forest plot in the active graphics window (using grid graphics system).

Usage

```
## S3 method for class 'netcomb'
forest(
  x,
  pooled = ifelse(x$random, "random", "common"),
  reference.group = x$reference.group,
  baseline.reference = x$baseline.reference,
  equal.size = gs("equal.size"),
  leftcols = "studlab",
  leftlabs = "Treatment",
  rightcols = c("effect", "ci"),
  rightlabs = NULL,
  digits = gs("digits.forest"),
  smlab = NULL,
  sortvar = x$seq,
  overall.hetstat = gs("overall.hetstat"),
  backtransf = x$backtransf,
  lab.NA = gs("lab.NA"),
  add.data,
  addrows.below.overall = if (x$overall.hetstat) 2 else gs("addrows.below.overall"),
  drop.reference.group = gs("drop.reference.group"),
  ...
)

## S3 method for class 'netcomb'
plot(x, ...)
```

Arguments

<code>x</code>	An object of class <code>netcomb</code> .
<code>pooled</code>	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
<code>reference.group</code>	Reference treatment(s).
<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa.
<code>equal.size</code>	A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
<code>leftcols</code>	A character vector specifying (additional) columns to be plotted on the left side of the forest plot or a logical value (see forest.meta help page for details).
<code>leftlabs</code>	A character vector specifying labels for (additional) columns on left side of the forest plot (see forest.meta help page for details).
<code>rightcols</code>	A character vector specifying (additional) columns to be plotted on the right side of the forest plot or a logical value (see forest.meta help page for details).
<code>rightlabs</code>	A character vector specifying labels for (additional) columns on right side of the forest plot (see forest.meta help page for details).

<code>digits</code>	Minimal number of significant digits for treatment effects and confidence intervals, see <code>print.default</code> .
<code>smlab</code>	A label printed at top of figure. By default, text indicating either common or random effects model is printed.
<code>sortvar</code>	An optional vector used to sort the individual studies (must be of same length as the total number of treatments).
<code>overall.hetstat</code>	A logical indicating whether to print heterogeneity measures.
<code>backtransf</code>	A logical indicating whether results should be back transformed in forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>lab.NA</code>	A character string to label missing values.
<code>add.data</code>	An optional data frame with additional columns to print in forest plot (see Details).
<code>addrows.below.overall</code>	A numeric value indicating how many empty rows are printed between meta-analysis results and heterogeneity statistics.
<code>drop.reference.group</code>	A logical indicating whether the reference group should be printed in the forest plot.
<code>...</code>	Additional arguments for <code>forest.meta</code> function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window.

Argument `sortvar` can be either a numeric or character vector with length of number of treatments. If `sortvar` is numeric the `order` function is utilised internally to determine the order of values. If `sortvar` is character it must be a permutation of the treatment names. It is also possible to sort by treatment comparisons (`sortvar = TE`, etc.), standard error (`sortvar = seTE`), and number of studies with direct treatment comparisons (`sortvar = k`).

Argument `add.data` can be used to add additional columns to the forest plot. This argument must be a data frame with the same row names as the treatment effects matrices in R object `x`, i.e., `x$TE.common` or `x$TE.random`.

For more information see help page of `forest.meta` function.

  lab.NA = gs("lab.NA"),
  equal.size = gs("equal.size"),
  ...
)

## S3 method for class 'netcomparison'
plot(x, ...)
```

Arguments

x	An object of class netcomparison.
pooled	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
leftcols	A character vector specifying (additional) columns to be plotted on the left side of the forest plot or a logical value (see forest.meta help page for details).
leftlabs	A character vector specifying labels for (additional) columns on left side of the forest plot (see forest.meta help page for details).
rightcols	A character vector specifying (additional) columns to be plotted on the right side of the forest plot or a logical value (see forest.meta help page for details).
rightlabs	A character vector specifying labels for (additional) columns on right side of the forest plot (see forest.meta help page for details).

nchar.comps	A numeric defining the minimum number of characters used to create unique names for components.
digits	Minimal number of significant digits for treatment effects and confidence intervals, see print.default.
digits.stat	Minimal number of significant digits for tests of overall effect, see print.default.
digits.pval	Minimal number of significant digits for p-value of overall effects, see print.default.
smlab	A label printed at top of figure. By default, text indicating either common or random effects model is printed.
backtransf	A logical indicating whether results should be back transformed in forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
lab.NA	A character string to label missing values.
equal.size	A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
...	Additional arguments for forest.meta function.

  ...
)

## S3 method for class 'netmeta'
plot(x, ...)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>pooled</code>	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
<code>reference.group</code>	Reference treatment(s).
<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa.
<code>labels</code>	An optional vector with treatment labels.
<code>equal.size</code>	A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
<code>leftcols</code>	A character vector specifying columns to be plotted on the left side of the forest plot or a logical value (see Details).
<code>leftlabs</code>	A character vector specifying labels for (additional) columns on left side of the forest plot (see Details).
<code>rightcols</code>	A character vector specifying columns to be plotted on the right side of the forest plot or a logical value (see Details).
<code>rightlabs</code>	A character vector specifying labels for (additional) columns on right side of the forest plot (see Details).
<code>digits</code>	Minimal number of significant digits for treatment effects and confidence intervals, see <code>print.default</code> .
<code>small.values</code>	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect, can be abbreviated; see netrank .
<code>nsim</code>	Number of simulations to calculate SUCRAs.
<code>digits.prop</code>	Minimal number of significant digits for P-scores, SUCRAs and direct evidence proportions, see <code>print.default</code> and netrank .
<code>smlab</code>	A label printed at top of figure. By default, text indicating either common or random effects model is printed.
<code>sortvar</code>	An optional vector used to sort treatments (must be of same length as the total number of treatments).
<code>overall.hetstat</code>	A logical indicating whether to print heterogeneity measures.
<code>print.tau2</code>	A logical value indicating whether to print the value of the between-study variance τ^2 .
<code>print.tau</code>	A logical value indicating whether to print τ , the square root of the between-study variance τ^2 .
<code>print.I2</code>	A logical value indicating whether to print the value of the I-squared statistic.
<code>backtransf</code>	A logical indicating whether results should be back transformed in forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.

lab.NA	A character string to label missing values.
add.data	An optional data frame with additional columns to print in forest plot (see Details).
addrows.below.overall	A numeric value indicating how many empty rows are printed between meta-analysis results and heterogeneity statistics.
drop.reference.group	A logical indicating whether the reference group should be printed in the forest plot.
col.subgroup	The colour to print information on subgroups.
print.subgroup.name	A logical indicating whether the name of the grouping variable should be printed in front of the group labels.
...	Additional arguments for <code>forest.meta</code> function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window.

Argument `sortvar` can be either a numeric or character vector with length of number of treatments. If `sortvar` is numeric the `order` function is utilised internally to determine the order of values. If `sortvar` is character it must be a permutation of the treatment names. It is also possible to provide either `sortvar = Pscore`, `sortvar = "Pscore"`, `sortvar = -Pscore`, or `sortvar = "-Pscore"` in order to sort treatments according to the ranking generated by `netrank` which is called internally. It is also possible to use "SUCRA" instead of "Pscore". Similar expressions are possible to sort by treatment comparisons (`sortvar = TE`, etc.), standard error (`sortvar = seTE`), number of studies with direct treatment comparisons (`sortvar = k`), and direct evidence proportion (`sortvar = prop.direct`, see also `netmeasures`).

The arguments `leftcols` and `rightcols` can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. The following columns are available:

Name	Definition
"studlab"	Treatments
"TE"	Network estimates (either from common or random effects model)
"seTE"	Corresponding standard errors
"Pscore"	P-scores (see <code>netrank</code>)
"SUCRA"	SUCRAs (see <code>netrank</code>)
"n.trts"	Number of participants per treatment arm
"k"	Number of studies in pairwise comparisons
"prop.direct"	Direct evidence proportions (see <code>netmeasures</code>)
"effect"	(Back-transformed) network estimates
"ci"	Confidence intervals
"effect.ci"	(Back-transformed) network estimates and confidence intervals

As a sidenote, the rather odd column name "studlab" to describe the treatment comparisons comes from internally calling `forest.meta` which uses study labels as the essential information.

Argument `add.data` can be used to add additional columns to the forest plot. This argument must be a data frame with row names equal to the treatment names in R object `x`, i.e., `x$trts`.

See help page of [forest.meta](#) for more information on the generation of forest plots and additional arguments.

    smlab,
    ...
)

## S3 method for class 'netsplit'
plot(x, ...)

```

Arguments

x	An object of class netsplit.
pooled	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
show	A character string indicating which comparisons should be printed (see Details).
subgroup	A character string indicating which layout should be used in forest plot: subgroups by comparisons ("comparison") or subgroups by estimates ("estimate"). Can be abbreviated.
overall	A logical indicating whether network meta-analysis estimates should be printed.
direct	A logical indicating whether direct estimates should be printed.
indirect	A logical indicating whether indirect estimates should be printed.
prediction	A logical indicating whether prediction intervals should be printed.
only.reference	A logical indicating whether only comparisons with the reference group should be printed.
sortvar	An optional vector used to sort comparisons (must be of same length as the total number of comparisons).
subset	An optional logical vector specifying a subset of comparisons to print (must be of same length as the total number of comparisons) .
text.overall	A character string used in the plot to label the network estimates.
text.direct	A character string used in the plot to label the direct estimates.
text.indirect	A character string used in the plot to label the indirect estimates.
text.predict	A character string used in the plot to label the prediction interval.

<code>type.overall</code>	A character string specifying how to plot treatment effects and confidence intervals for the overall network evidence.
<code>type.direct</code>	A character string specifying how to plot treatment effects and confidence intervals for the direct evidence.
<code>type.indirect</code>	A character string specifying how to plot treatment effects and confidence intervals for the indirect evidence.
<code>col.square</code>	The colour for squares.
<code>col.square.lines</code>	The colour for the outer lines of squares.
<code>col.inside</code>	The colour for results and confidence limits if confidence limits are completely within squares squares.
<code>col.diamond</code>	The colour of diamonds.
<code>col.diamond.lines</code>	The colour of the outer lines of diamonds.
<code>col.predict</code>	Background colour of prediction intervals.
<code>col.predict.lines</code>	Colour of outer lines of prediction intervals.
<code>col.subgroup</code>	The colour to print information on subgroups, i.e., pairwise comparisons.
<code>equal.size</code>	A logical indicating whether all squares should be of equal size. Otherwise, the square size is proportional to the precision of estimates.
<code>leftcols</code>	A character vector specifying columns to be plotted on the left side of the forest plot (see Details).
<code>leftlabs</code>	A character vector specifying labels for columns on left side of the forest plot.
<code>rightcols</code>	A character vector specifying columns to be plotted on the right side of the forest plot (see Details).
<code>rightlabs</code>	A character vector specifying labels for columns on right side of the forest plot.
<code>digits</code>	Minimal number of significant digits for treatment effects and confidence intervals, see <code>print.default</code> .
<code>digits.prop</code>	Minimal number of significant digits for the direct evidence proportion.
<code>backtransf</code>	A logical indicating whether results should be back transformed in forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>lab.NA</code>	A character string to label missing values.
<code>smlab</code>	A label printed at top of figure. By default, text indicating either common or random effects model is printed.
<code>...</code>	Additional arguments for <code>forest.meta</code> function.

Details

A forest plot, also called confidence interval plot, is drawn in the active graphics window.

The arguments `leftcols` and `rightcols` can be used to specify columns which are plotted on the left and right side of the forest plot, respectively. If argument `rightcols` is `FALSE`, no columns will be plotted on the right side.

If direct estimates are included in the forest plot (`direct = TRUE`, default), the following columns will be printed on the left side of the forest plot: the comparisons (column "studlab" in [forest.meta](#)), number of pairwise comparisons ("k"), direct evidence proportion ("k"), and I^2 from pairwise comparison ("I2").

If direct estimates are not included in the forest plot (`direct = FALSE`), only the comparisons ("studlab") are printed on the left side of the forest plot.

For more information see help page of [forest.meta](#) function.

Argument `show` determines which comparisons are printed:

"all"	All comparisons
"both"	Only comparisons contributing both direct and indirect evidence
"with.direct"	Comparisons providing direct evidence
"direct.only"	Comparisons providing only direct evidence
"indirect.only"	Comparisons providing only indirect evidence

## End(Not run)
```

Description

Network meta-analysis comparing the effects of a number of treatments for Parkinson's disease.

The data are the mean lost work-time reduction in patients given dopamine agonists as adjunct therapy in Parkinson's disease (Franchini et al. 2012). The data are given as sample size, mean and standard deviation in each trial arm. Treatments are placebo and four active drugs. These data are used as an example in the supplemental material of Dias et al. (2013) where placebo is coded as 1 and the four active drugs as 2 to 5.

Format

A data frame with the following columns:

Study	study label
Treatment1	treatment 1
y1	treatment effect arm 1
sd1	Standard deviation arm 1
n1	Sample size arm 1
Treatment2	treatment 2
y2	treatment effect arm 2
sd2	Standard deviation arm 2
n2	Sample size arm 2
Treatment3	treatment 3
y3	treatment effect arm 3
sd3	Standard deviation arm 3
n3	Sample size arm 3

Note

The dataset Franchini2012 is identical to dataset [dat.franchini2012](#) in R package **metadat**.

  linreg = FALSE,
  rank = FALSE,
  mm = FALSE,
  ...
)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>order</code>	A mandatory character or numerical vector specifying the order of treatments or list of comparators (see <code>Details</code>).
<code>pooled</code>	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
<code>xlab</code>	A label for the x-axis.
<code>level</code>	The confidence level utilised in the plot. For the funnel plot, confidence limits are not drawn if <code>yaxis = "size"</code> .
<code>pch</code>	The plotting symbol(s) used for individual studies within direct comparisons.
<code>col</code>	The colour(s) used for individual studies within direct comparisons.
<code>legend</code>	A logical indicating whether a legend with information on direct comparisons should be added to the plot.
<code>pos.legend</code>	The position of the legend describing plotting symbols and colours for direct comparisons.
<code>pos.tests</code>	The position of results for test(s) of funnel plot asymmetry.
<code>lump.comparator</code>	A logical indicating whether comparators should be lumped, e.g., to specify inactive treatments. information on direct comparisons should be added to the plot.
<code>text.comparator</code>	A character string used in the plot to label the comparator if <code>lump.comparator</code> is TRUE.
<code>method.bias</code>	A character vector indicating which test(s) for funnel plot asymmetry to use. Admissible values are "Begg", "Egger", and "Thompson", can be abbreviated. See function <code>metabias</code> .
<code>text.linreg</code>	A character string used in the plot to label the Egger test for funnel plot asymmetry.
<code>text.rank</code>	A character string used in the plot to label the Begg test for funnel plot asymmetry.
<code>text.mm</code>	A character string used in the plot to label the Thompson-Sharp test for funnel plot asymmetry.
<code>sep.trts</code>	A character used in comparison names as separator between treatment labels.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names (see <code>netmeta</code>).
<code>backtransf</code>	A logical indicating whether results for relative summary measures (argument <code>sm</code> equal to "OR", "RR", "HR", or "IRR") should be back transformed in funnel plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are printed as odds ratios rather than log odds ratios, for example.
<code>digits.pval</code>	Minimal number of significant digits for p-value of test(s) for funnel plot asymmetry.

warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
linreg	Deprecated argument (replaced by <code>method.bias</code>).
rank	Deprecated argument (replaced by <code>method.bias</code>).
mm	Deprecated argument (replaced by <code>method.bias</code>).
...	Additional graphical arguments passed as arguments to funnel.meta .

Details

A ‘comparison-adjusted’ funnel plot (Chaimani & Salanti, 2012) is drawn in the active graphics window.

Argument order is mandatory to determine the order of treatments (Chaimani et al., 2013):

“Before using this plot, investigators should order the treatments in a meaningful way and make assumptions about how small studies differ from large ones. For example, if they anticipate that newer treatments are favored in small trials, then they could name the treatments from oldest to newest so that all comparisons refer to ‘old versus new intervention’. Other possibilities include defining the comparisons so that all refer to an active treatment versus placebo or sponsored versus non-sponsored intervention.”

Alternatively, it is possible to only provide a single or few treatment name(s) in argument order to define the comparator(s). In this case only comparisons with this / these treatment(s) will be considered. If argument `lump.comparator` is TRUE, all comparators will be lumped into a single group. The text for this group can be specified with argument `text.comparator`.

In the funnel plot, if `yaxis` is “se”, the standard error of the treatment estimates is plotted on the y-axis which is likely to be the best choice (Sterne & Egger, 2001). Other possible choices for `yaxis` are “invvar” (inverse of the variance), “invse” (inverse of the standard error), and “size” (study size).

Value

A data frame with the following columns:

<code>studlab</code>	Study label.
<code>treat1</code>	Label/Number for first treatment.
<code>treat2</code>	Label/Number for second treatment.
<code>comparison</code>	Treatment comparison.
<code>TE</code>	Estimate of treatment effect, e.g., log odds ratio.
<code>TE.direct</code>	Pooled estimate from direct evidence.
<code>TE.adj</code>	‘Comparison-adjusted’ treatment effect (TE - TE.direct).
<code>seTE</code>	Standard error of treatment estimate.
<code>pch</code>	Plotting symbol(s).
<code>col</code>	Colour of plotting symbol(s).

Gurusamy2011

Network meta-analysis on blood loss during liver transplantation

Description

Network meta-analysis comparing the effects of a number of interventions for decreasing blood loss and blood transfusion requirements during liver transplantation.

Format

A data frame with the following columns:

<i>study</i>	study information (first author, year)
<i>treatment</i>	treatment
<i>death</i>	mortality at 60 days post-transplantation
<i>n</i>	number of individuals in treatment arm

Note

The dataset Gurusamy2011 is identical to dataset [dat.gurusamy2011](#) in R package **metadat**.

hasse.netposet	<i>Hasse diagram</i>
----------------	----------------------

Description

This function generates a Hasse diagram for a partial order of treatment ranks in a network meta-analysis.

Usage

```
## S3 method for class 'netposet'
hasse(
  x,
  pooled = ifelse(x$random, "random", "common"),
  newpage = TRUE,
  shape = "roundrect",
  col.lines = "black",
  col.nodes = "black",
  lwd = 1,
  ...
)

hasse(x, ...)
```

Arguments

x	An object of class netposet (mandatory).
pooled	A character string indicating whether Hasse diagram show be drawn for common ("common") or random effects model ("random"). Can be abbreviated.
newpage	A logical value indicating whether a new figure should be printed in an existing graphics window. Otherwise, the Hasse diagram is added to the existing figure.
shape	Shape of node borders, either "roundrect", "rect", or "none", can be abbreviated.
col.lines	Line colour.
col.nodes	Colour for treatment node borders.
lwd	Width of lines and node borders.
...	Additional arguments (ignored).

Details

Generate a Hasse diagram (Carlsen & Bruggemann, 2014) for a partial order of treatment ranks in a network meta-analysis (Rücker & Schwarzer, 2017).

This R function is a wrapper function for a modified version of R function `hasse` in R package **hasseDiagram** (Krzysztof Ciomek, <https://github.com/kciomek/hasseDiagram>) which is available under the MIT license.

hatmatrix

Derive hat matrix from network meta-analysis

Description

Auxiliary function to derive hat matrix from network meta-analysis

Usage

```

hatmatrix(
  x,
  method = "Ruecker",
  type,
  common = x$common,
  random = x$random,
  nchar.trts = x$nchar.trts,
  nchar.studlab = x$nchar.studlab
)

## S3 method for class 'hatmatrix'
print(
  x,
  common = x$x$common,
  random = x$x$random,
  nchar.trts = x$x$nchar.trts,
  nchar.studlab = x$x$nchar.studlab,
  digits = gs("digits"),
  legend = gs("legend"),
  legend.studlab = TRUE,
  ...
)

```

Arguments

x	A netmeta object.
method	A character string indicating which method is used to derive the hat matrix. Either "Ruecker", "Krahn" or "Davies" (can be abbreviated, see Details).
type	A character string indicating which specific hat matrix should be derived (can be abbreviated, see Details).
common	A logical indicating whether a hat matrix should be printed for the common effects network meta-analysis.
random	A logical indicating whether a hat matrix should be printed for the random effects network meta-analysis.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
nchar.studlab	A numeric defining the minimum number of characters used to create unique study labels.
digits	Minimal number of significant digits, see <code>print.default</code> .
legend	A logical indicating whether a legend should be printed.
legend.studlab	A logical indicating whether a legend should be printed for abbreviated study labels.
...	Additional arguments (ignored).

Details

This auxiliary function can be used to derive various hat matrices from a network meta-analysis object.

Hat matrix by Rücker (2012):

This hat matrix is estimated if `method = "Ruecker"`.

Let n be the number of different treatments (nodes, vertices) in a network and let m be the number of existing comparisons (edges) between the treatments. If there are only two-arm studies, m is equal to the number of studies, k . Let `seTE.adj.common` and `seTE.adj.random` be the vectors of adjusted standard errors under the common and random effects model (see [netmeta](#)). Let \mathbf{W} be the $m \times m$ diagonal matrix that contains the inverse variance $1 / \text{seTE.adj.common}^2$ or $1 / \text{seTE.adj.random}^2$.

The given comparisons define the network structure. Therefrom an $m \times n$ design matrix \mathbf{X} (edge-vertex incidence matrix) is formed; for more precise information, see Rücker (2012). Moreover, the $n \times n$ Laplacian matrix \mathbf{L} and its Moore-Penrose pseudoinverse \mathbf{L}^+ are calculated (both matrices play an important role in graph theory and electrical network theory). Using these matrices, the variances based on both direct and indirect comparisons can be estimated. The hat matrix \mathbf{H} is estimated by $\mathbf{H} = \mathbf{X}\mathbf{L}^+\mathbf{X}^T\mathbf{W} = \mathbf{X}(\mathbf{X}^T\mathbf{W}\mathbf{X})^+\mathbf{X}^T\mathbf{W}$.

Hat matrices by Krahn et al. (2013):

One of the following hat matrices is estimated if `method = "Krahn"`.

Use of `type = "design"` (default) results in a hat matrix of dimension $n(n-1)/2 \times s$, where s is the sum of the number of independent comparisons from each design.

Use of `type = "studies"` results in a hat matrix of dimension $n(n-1)/2 \times l$, where l is the number of independent pairwise comparisons, i.e., a three-arm study contributes two pairwise comparisons.

Hat matrices by Davies et al. (2022):

One of three hat matrices is estimated if `method = "Davies"`.

Here, we focus on the hat matrix of the aggregate (two-step) version of the graph theoretical NMA model. In the first step, a pairwise meta-analysis is performed across each edge using the adjusted weights (these account for correlations due to multi-arm trials). From this we obtain direct treatment effect estimates (and corresponding aggregate weights) associated with each edge. In step two, we combine these direct estimates in a network meta analysis to obtain the network estimates. This is done using weighted least squares regression. The hat matrix associated with this second step is called the *aggregate hat matrix*.

All three versions of the aggregate hat matrix contain the same information: the second two can be derived directly from the first. They differ in their dimensionality.

Each row of the hat matrix that represents a treatment comparison (ij) describes the flow of evidence through each edge for that comparison. This defines a directed acyclic 'flow graph' from node i to node j .

(1) Use of `type = "short"` (default) results in a hat matrix of dimension $e \times e$, where e is the number of (unique) edges (direct comparisons) in the network. This is the aggregate hat matrix described in Davies et al. (2022). Each row and column represents a pair of treatments for which there is at least one direct comparison.

(2) Use of `type = "long"` results in a hat matrix of dimension $n(n-1)/2 \times e$. There is a row for every possible pair of treatments in the network - regardless of whether there is direct evidence for this comparison. Each column represents a pair of treatments for which there is at least one direct comparison. The extra rows can be calculated from the short hat matrix using consistency equations.

(3) Use of `type = "full"` results in a hat matrix of dimension $n(n-1)/2 \times n(n-1)/2$. In comparison to the long hat matrix, columns of zeroes are added for comparisons that do not have any direct evidence. Therefore, there is a row and column for every pair of treatments in the network. This hat matrix is used to calculate the transition matrices for the random walk in [netcontrib](#).

Value

A list with two hat matrices: `common` (common effects model) and `random` (random effects model).

heatplot

Generic function for heat plots

Description

Generic function for heat plots

Usage

```
heatplot(x, ...)
```

Arguments

x	An R object.
...	Additional arguments.

Details

For more details, look at the following function to generate heat plots:

- [heatplot.netmeta](#)
- [heatplot.crossnma](#) (if installed)

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

Examples

```

data(Senn2013)

# Only consider first five studies (to reduce runtime of example)
#
studies <- unique(Senn2013$studlab)
Senn2013.5 <- subset(Senn2013, studlab %in% studies[1:5])

# Conduct random effects network meta-analysis with
# placebo as reference treatment
#
net1 <- netmeta(TE, seTE, treat1.long, treat2.long, studlab,
  data = Senn2013.5, sm = "MD", common = FALSE, reference = "plac")

# Generate a heat plot (with abbreviated treatment labels)
#
heatplot(net1, nchar.trts = 4)

```

heatplot.netmeta

Heat Plot

Description

Produces a heat plot containing treatment estimates with confidence intervals for all possible pairwise comparisons.

Usage

```

## S3 method for class 'netmeta'
heatplot(
  x,
  pooled = ifelse(x$random, "random", "common"),
  seq = x$seq,
  nchar.trts = x$nchar.trts,
  low.colour = "red",
  mid.colour = "white",
  high.colour = "springgreen4",
  size = 6,
  size.trt = 16,
  size.axis = 12,
  digits = gs("digits.forest"),
  backtransf = x$backtransf,
  ...
)

```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>pooled</code>	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
<code>seq</code>	A character or numerical vector specifying the sequence of treatments in rows and columns of the heat plot.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>low.colour</code>	A string indicating the colour of low relative treatment effects for the heat plot (e.g odds ratio of ~0.5)
<code>mid.colour</code>	A string indicating the colour of null relative treatment effects for the heat plot (e.g odds ratio of ~1.0).
<code>high.colour</code>	A string indicating the colour of high relative treatment effects for the heat plot (e.g odds ratio of ~2.0).
<code>size</code>	The size of cell entries with the relative treatment effect and confidence intervals.
<code>size.trt</code>	The size of treatment names placed on the top and left of the plot.
<code>size.axis</code>	The size of labels on the top and left of the plot
<code>digits</code>	Minimal number of significant digits for treatment effects and confidence intervals, see <code>print.default</code> .
<code>backtransf</code>	A logical indicating whether results should be back transformed in forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>...</code>	Additional arguments.

Value

League heat plot, where a color scale is used to represent the values of relative treatment effects.

Examples

```
data(Senn2013)

# Only consider first five studies (to reduce runtime of example)
#
studies <- unique(Senn2013$studlab)
Senn2013.5 <- subset(Senn2013, studlab %in% studies[1:5])

# Conduct random effects network meta-analysis with
# placebo as reference treatment
#
net1 <- netmeta(TE, seTE, treat1.long, treat2.long, studlab,
  data = Senn2013.5, sm = "MD", common = FALSE, reference = "plac")

# Generate a heat plot (with abbreviated treatment labels)
#
heatplot(net1, nchar.trts = 4)
```

`invmat`*Moore-Penrose Pseudoinverse of a Matrix*

Description

Calculates the Moore-Penrose pseudoinverse of a square matrix **X**.

Usage

```
invmat(X)
```

Arguments

X A square matrix.

Details

This function is used by default in R package **netmeta** to calculate the Moore-Penrose pseudoinverse \mathbf{L}^+ of the Laplacian matrix **L** (Rücker, 2012):

$\mathbf{L}^+ = (\mathbf{X} - \mathbf{J} / n)^{-1} + \mathbf{J} / n$ with identity matrix **J** of dimension $n \times n$.

Value

The Moore-Penrose pseudoinverse for matrix **X**.

merge.pairwise	<i>Merge pairwise object with additional data</i>
----------------	---

Description

Merge pairwise object with additional data, e.g., information on network connectivity.

Usage

```
## S3 method for class 'pairwise'
merge(x, y, all.x = TRUE, ...)
```

Arguments

x	An object of class pairwise.
y	A data frame or an object of class netconnection.
all.x	A logical indicating whether to keep all observations from the pairwise object, i.e., also include observations not belonging to a subnetwork due to missing estimates or standard errors.
...	Other arguments (passed on to merge).

Value

An object of class pairwise.

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

metabias.netmeta

Test of funnel plot asymmetry in network meta-analysis

Description

Test of funnel plot asymmetry in network meta-analysis

Usage

```
## S3 method for class 'netmeta'
metabias(
  x,
  order,
  pooled = ifelse(x$random, "random", "common"),
  method.bias = "Egger",
  lump.comparator = gs("lump.comparator"),
  ...
)
```

Arguments

x	An object of class netmeta.
order	A mandatory character or numerical vector specifying the order of treatments or list of comparators (see Details).
pooled	A character string indicating whether results for the common ("common") or random effects model ("random") should be used in test of funnel plot asymmetry. Can be abbreviated.
method.bias	A character vector indicating which test(s) for funnel plot asymmetry to use. Admissible values are "Begg", "Egger", and "Thompson", can be abbreviated. See function metabias.meta .

lump.comparator A logical indicating whether comparators should be lumped, e.g., to specify inactive treatments. information on direct comparisons should be added to the plot.

... Additional arguments (passed on to [metabias.meta](#)).

Details

Test of funnel plot asymmetry in network meta-analysis

Argument order is mandatory to determine the order of treatments (Chaimani et al., 2013):

“[...] investigators should order the treatments in a meaningful way and make assumptions about how small studies differ from large ones. For example, if they anticipate that newer treatments are favored in small trials, then they could name the treatments from oldest to newest so that all comparisons refer to ‘old versus new intervention’. Other possibilities include defining the comparisons so that all refer to an active treatment versus placebo or sponsored versus non-sponsored intervention.”

Alternatively, it is possible to only provide a single or few treatment name(s) in argument order to define the comparator(s). In this case only comparisons with this / these treatment(s) will be considered. If argument `lump.comparator` is TRUE, all comparators will be lumped into a single group.

Value

A list with class `metabias` containing the following components if a test for funnel plot asymmetry is conducted:

<code>statistic</code>	Test statistic.
<code>df</code>	The degrees of freedom of the test statistic in the case that it follows a t distribution.
<code>pval</code>	The p-value for the test.
<code>estimate</code>	Estimates used to calculate test statistic.
<code>method</code>	A character string indicating what type of test was used.
<code>title</code>	Title of Cochrane review.
<code>complab</code>	Comparison label.
<code>outclab</code>	Outcome label.
<code>var.model</code>	A character string indicating whether none, multiplicative, or additive residual heterogeneity variance was assumed.
<code>method.bias</code>	As defined above.
<code>x</code>	Network meta-analysis object.
<code>version</code>	Version of R package meta used to create object.
<code>version.netmeta</code>	Version of R package netmeta used to create object.

Or a list with the following elements if test is not conducted due to the number of studies:

<code>k</code>	Number of comparisons.
----------------	------------------------

k.min Minimum number of comparisons to perform test for funnel plot asymmetry.
 version Version of R package **meta** used to create object.
 version.netmeta Version of R package **netmeta** used to create object.

netbind

Combine network meta-analysis objects

Description

This function can be used to combine network meta-analysis objects which is especially useful to generate a forest plot with results of several network meta-analyses.

Usage

```
netbind(
  ...,
  name,
  common,
  random,
  col.study = "black",
  col.inside = "white",
  col.square = "gray",
  col.square.lines = col.square,
  backtransf,
  reference.group,
  baseline.reference,
  warn.deprecated = gs("warn.deprecated"),
  fixed,
  comb.fixed,
  comb.random
)
```

Arguments

...	Any number of network meta-analysis objects or a single list with network meta-analyses.
name	An optional character vector providing descriptive names for network meta-analysis objects.
common	A logical indicating whether results for the common effects model should be reported.
random	A logical indicating whether results for the random effects model should be reported.
col.study	The colour for network estimates and confidence limits.
col.inside	The colour for network estimates and confidence limits if confidence limits are completely within squares.
col.square	The colour for squares.
col.square.lines	The colour for the outer lines of squares.

backtransf	A logical indicating whether results should be back transformed. If backtransf = TRUE (default), results for sm = "OR" are printed as odds ratios rather than log odds ratios, for example.
reference.group	Reference treatment.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if reference.group has been specified.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
fixed	Deprecated argument; replaced by common.
comb.fixed	Deprecated argument; replaced by common.
comb.random	Deprecated argument; replaced by random.

Value

An object of class "netbind" with corresponding forest function. The object is a list containing the following components:

common	A data frame with results for the common effects model.
random	A data frame with results for the random effects model.
sm	Summary measure used in network meta-analyses.
level.ma	Level for confidence intervals.
reference.group, baseline.reference	As defined above.

```

netcomb

Additive network meta-analysis for combinations of treatments

Description

Some treatments in a network meta-analysis may be combinations of other treatments or have common components. The influence of individual components can be evaluated in an additive network meta-analysis model assuming that the effect of treatment combinations is the sum of the effects of its components. This function implements this additive model in a frequentist way.

Usage

```

netcomb(
  x,
  inactive = NULL,
  sep.comps = gs("sep.comps"),
  C.matrix,
  common = x$common,
  random = x$random | !is.null(tau.preset),
  tau.preset = NULL,

```

```

details.chkident = FALSE,
nchar.comps = x$nchar.trts,
sep.ia = gs("sep.ia"),
func.inverse = invmat,
overall.hetstat = x$overall.hetstat,
backtransf = x$backtransf,
na.unident = gs("na.unident"),
warn.deprecated = gs("warn.deprecated"),
...
)

```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>inactive</code>	A character string defining the inactive treatment component (see Details).
<code>sep.comps</code>	A single character to define separator between treatment components.
<code>C.matrix</code>	C matrix (see Details).
<code>common</code>	A logical indicating whether a common effects network meta-analysis should be conducted.
<code>random</code>	A logical indicating whether a random effects network meta-analysis should be conducted.
<code>tau.preset</code>	An optional value for the square-root of the between-study variance τ^2 .
<code>details.chkident</code>	A logical indicating whether details on unidentifiable components should be printed.
<code>nchar.comps</code>	A numeric defining the minimum number of characters used to create unique names for components (see Details).
<code>sep.ia</code>	A single character to define separator for interactions.
<code>func.inverse</code>	R function used to calculate the pseudoinverse of the Laplacian matrix L (see netmeta).
<code>overall.hetstat</code>	A logical indicating whether to print heterogeneity measures.
<code>backtransf</code>	A logical indicating whether results should be back transformed in printouts and forest plots.
<code>na.unident</code>	A logical indicating whether unidentifiable components and combinations should be set to missing values.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments (to catch deprecated arguments).

Details

Treatments in network meta-analysis (NMA) can be complex interventions. Some treatments may be combinations of others or have common components. The standard analysis provided by `netmeta` is a NMA where all existing (single or combined) treatments are considered as different nodes in the network. Exploiting the fact that some treatments are combinations of common components, an additive component network meta-analysis (CNMA) model can be used to evaluate the influence of individual components. This model assumes that the effect of a treatment combination is the sum of the effects of its components which implies that common components cancel out in comparisons.

The additive CNMA model has been implemented using Bayesian methods (Mills et al., 2012; Welton et al., 2013). This function implements the additive model in a frequentist way (Rücker et al., 2020).

The underlying multivariate model is given by

$$\delta = B\theta, \theta = C\beta$$

with

δ vector of true treatment effects (differences) from individual studies,

B design matrix describing the structure of the network,

θ parameter vector that represents the existing combined treatments,

C matrix describing how the treatments are composed,

β parameter vector representing the treatment components.

All parameters are estimated using weighted least squares regression.

Argument `inactive` can be used to specify a single component that does not have any therapeutic value. Accordingly, it is assumed that the treatment effect of the combination of this component with an additional treatment component is equal to the treatment effect of the additional component alone.

Argument `sep.comps` can be used to specify the separator between individual components. By default, the matrix C is calculated internally from treatment names. However, it is possible to specify a different matrix using argument `C.matrix`.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

Value

An object of class `netcomb` with corresponding `print`, `summary`, and `forest` functions. The object is a list containing the following components:

<code>studlab</code>	Study labels.
<code>treat1</code>	Label/Number for first treatment.
<code>treat2</code>	Label/Number for second treatment.
<code>TE</code>	Estimate of treatment effect, i.e. difference between first and second treatment.

seTE	Standard error of treatment estimate.
seTE.adj.common, seTE.adj.random	Standard error of treatment estimate, adjusted for multi-arm studies.
design	Design of study providing pairwise comparison.
event1	Number of events in first treatment group.
event2	Number of events in second treatment group.
n1	Number of observations in first treatment group.
n2	Number of observations in second treatment group.
k	Total number of studies.
m	Total number of pairwise comparisons.
n	Total number of treatments.
d	Total number of designs (corresponding to the unique set of treatments compared within studies).
c	Total number of components.
trts	Treatments included in network meta-analysis.
k.trts	Number of studies evaluating a treatment.
n.trts	Number of observations receiving a treatment (if arguments n1 and n2 are provided).
events.trts	Number of events observed for a treatment (if arguments event1 and event2 are provided).
studies	Study labels coerced into a factor with its levels sorted alphabetically.
narms	Number of arms for each study.
designs	Unique list of designs present in the network. A design corresponds to the set of treatments compared within a study.
comps	Unique list of components present in the network.
TE.nma.common, TE.nma.random	A vector of length m of consistent treatment effects estimated by network meta-analysis (nma) (common and random effects model).
seTE.nma.common, seTE.nma.random	A vector of length m of effective standard errors estimated by network meta-analysis (common and random effects model).
lower.nma.common, lower.nma.random	A vector of length m of lower confidence interval limits for consistent treatment effects estimated by network meta-analysis (common and random effects model).
upper.nma.common, upper.nma.random	A vector of length m of upper confidence interval limits for the consistent treatment effects estimated by network meta-analysis (common and random effects model).
statistic.nma.common, statistic.nma.random	A vector of length m of z-values for test of treatment effect for individual comparisons (common and random effects model).

`pval.nma.common`, `pval.nma.random`
 A vector of length m of p-values for test of treatment effect for individual comparisons (common and random effects model).

`TE.cnma.common`, `TE.cnma.random`
 A vector of length m of consistent treatment effects estimated by the additive (common and random effects) model.

`seTE.cnma.common`, `seTE.cnma.random`
 A vector of length m with standard errors estimated by the additive (common and random effects) model.

`lower.cnma.common`, `lower.cnma.random`
 A vector of length m of lower confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.

`upper.cnma.common`, `upper.cnma.random`
 A vector of length m of upper confidence interval limits for consistent treatment effects estimated by the additive (common and random effects) model.

`statistic.cnma.common`, `statistic.cnma.random`
 A vector of length m of z-values for the test of an overall effect estimated by the additive (common and random effects) model.

`pval.cnma.common`, `pval.cnma.random`
 A vector of length m of p-values for the test of an overall effect estimated by the additive (common and random effects) model.

`TE.common`, `TE.random`
 $n \times n$ matrix with overall treatment effects estimated by the additive (common and random effects) model.

`seTE.common`, `seTE.random`
 $n \times n$ matrix with standard errors estimated by the additive (common and random effects) model.

`lower.common`, `upper.common`, `lower.random`, `upper.random`
 $n \times n$ matrices with lower and upper confidence interval limits estimated by the additive (common and random effects) model.

`statistic.common`, `pval.common`, `statistic.random`, `pval.random`
 $n \times n$ matrices with z-values and p-values for test of overall effect estimated by the additive (common and random effects) model.

`Comp.common`, `Comp.random`
 A vector of component effects (common and random effects model).

`seComp.common`, `seComp.random`
 A vector with corresponding standard errors (common and random effects model).

`lower.Comp.common`, `lower.Comp.random`
 A vector with lower confidence limits for components (common and random effects model).

`upper.Comp.common`, `upper.Comp.random`
 A vector with upper confidence limits for components (common and random effects model).

`statistic.Comp.common`, `statistic.Comp.random`
 A vector with z-values for the overall effect of components (common and random effects model).

pval.Comp.common, pval.Comp.random	A vector with p-values for the overall effect of components (common and random effects model).
Comb.common, Comb.random	A vector of combination effects (common and random effects model).
seComb.common, seComb.random	A vector with corresponding standard errors (common and random effects model).
lower.Comb.common, lower.Comb.random	A vector with lower confidence limits for combinations (common and random effects model).
upper.Comb.common, upper.Comb.random	A vector with upper confidence limits for combinations (common and random effects model).
statistic.Comb.common, statistic.Comb.random	A vector with z-values for the overall effect of combinations (common and random effects model).
pval.Comb.common, pval.Comb.random	A vector with p-values for the overall effect of combinations (common and random effects model).
Q.additive	Overall heterogeneity / inconsistency statistic (additive model).
df.Q.additive	Degrees of freedom for test of heterogeneity / inconsistency (additive model).
pval.Q.additive	P-value for test of heterogeneity / inconsistency (additive model).
tau	Square-root of between-study variance (additive model).
I2, lower.I2, upper.I2	I-squared, lower and upper confidence limits.
Q.standard	Overall heterogeneity / inconsistency statistic (standard model).
df.Q.standard	Degrees of freedom for test of heterogeneity / inconsistency (standard model).
pval.Q.standard	P-value for test of heterogeneity / inconsistency (standard model).
Q.diff	Test statistic for difference in goodness of fit between standard and additive model.
df.Q.diff	Degrees of freedom for difference in goodness of fit between standard and additive model.
pval.Q.diff	P-value for difference in goodness of fit between standard and additive model.
A.matrix	Adjacency matrix ($n \times n$).
B.matrix	Edge-vertex incidence matrix ($m \times n$).
C.matrix	As defined above.
sm	Summary measure.
level.ma	Level for confidence intervals.
common, random, tau.preset	As defined above.
sep.trts	A character used in comparison names as separator between treatment labels.

nchar.comps	A numeric defining the minimum number of characters used to create unique component names.
inactive, sep.comps, sep.ia	As defined above.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots.
title	Title of meta-analysis / systematic review.
x	As defined above.
call	Function call.
version	Version of R package netmeta used to create object.

Note

This function calculates effects for individual components and complex interventions present in the network.

R function [netcomplex](#) can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis. Furthermore, R function [netcomparison](#) can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

...
)

```

Arguments

x	An object of class <code>netcomb</code> or <code>netcomparison</code> (print function).
treat1	A character vector defining the first complex intervention(s).
treat2	A character vector defining the second complex intervention(s).
common	A logical indicating whether results for common effects model should be conducted.
random	A logical indicating whether results for random effects model should be conducted.
level	The level used to calculate confidence intervals for combinations of components.
nchar.comps	A numeric defining the minimum number of characters used to create unique names for components (see <code>Details</code>).
backtransf	A logical indicating whether printed results should be back transformed. If <code>backtransf=TRUE</code> , results for <code>sm="OR"</code> are printed as odds ratios rather than log odds ratios.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).
digits	Minimal number of significant digits, see <code>print.default</code> .
digits.stat	Minimal number of significant digits for z-value of test for overall effect, see <code>print.default</code> .
digits.pval	Minimal number of significant digits for p-values, see <code>print.default</code> .
scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval	A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval	A logical specifying whether p-values for test of combination effect should be printed according to JAMA reporting standards.
big.mark	A character used as thousands separator.
legend	A logical indicating whether a legend should be printed.

Details

R functions `netcomb` and `discomb` calculate effects for individual components and complex interventions present in the component network meta-analysis (CNMA). This function can be used to calculate the effect for comparisons of two arbitrary complex interventions defined by arguments `treat1` and `treat2`.

All complex interventions occurring in the network are considered for the first complex intervention if argument `treat1` is missing. The reference group defined in the (C)NMA is used as second complex intervention if argument `treat2` is missing. The first complex intervention in the (C)NMA is used if the reference group is not defined.

The following matrices are needed to calculate comparison effects of arbitrary complex interventions, (Rücker et al., 2020, Section 3.2):

- B matrix describing how comparisons are composed by complex interventions,
- C matrix describing how the complex interventions are composed by the components.

Internally, both matrices are constructed based on arguments `x`, `treat1` and `treat2`.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

Value

A list is returned by the function `netcomparison` with the following elements:

<code>comparison</code>	Comparison.
<code>TE.common</code> , <code>TE.random</code>	A vector of comparison effects (common and random effects model).
<code>seTE.common</code> , <code>seTE.random</code>	A vector with corresponding standard errors (common and random effects model).
<code>lower.common</code> , <code>lower.random</code>	A vector with lower confidence limits for comparisons (common and random effects model).
<code>upper.common</code> , <code>upper.random</code>	A vector with upper confidence limits for comparisons (common and random effects model).
<code>statistic.common</code> , <code>statistic.random</code>	A vector with z-values for the overall effect of comparisons (common and random effects model).
<code>pval.common</code> , <code>pval.random</code>	A vector with p-values for the overall effect of comparisons (common and random effects model).
<code>trts</code>	Treatments included in comparisons.
<code>comps</code>	Components included in comparisons.
<code>treat1</code> , <code>treat2</code>	A defined above.
<code>common</code> , <code>random</code>	A defined above.

```
level, nchar.comps, backtransf, x
      A defined above.
B.matrix      B matrix.
C.matrix      C matrix.
```

Note

R function [netcomplex](#) can be used to calculate the effect for arbitrary complex interventions in a component network meta-analysis.

netcomplex

Calculate effect of arbitrary complex interventions in component network meta-analysis

Description

Calculate effect of arbitrary complex interventions (i.e., combinations of several components) in component network meta-analysis.

Usage

```

netcomplex(
  x,
  complex,
  common = x$common,

```

```

    random = x$random,
    level = x$level.ma,
    nchar.comps = x$nchar.trts,
    backtransf = x$backtransf,
    warn.deprecated = gs("warn.deprecated"),
    ...
)

## S3 method for class 'netcomplex'
print(
  x,
  common = x$common,
  random = x$random,
  backtransf = x$backtransf,
  nchar.comps = x$nchar.comps,
  digits = gs("digits"),
  digits.stat = gs("digits.stat"),
  digits.pval = gs("digits.pval"),
  scientific.pval = gs("scientific.pval"),
  zero.pval = gs("zero.pval"),
  JAMA.pval = gs("JAMA.pval"),
  big.mark = gs("big.mark"),
  legend = gs("legend"),
  warn.deprecated = gs("warn.deprecated"),
  ...
)

```

Arguments

x	An object of class netcomb or netcomplex (print function).
complex	A matrix, vector or single numeric defining the complex intervention(s) (see Details).
common	A logical indicating whether results for common effects model should be conducted.
random	A logical indicating whether results for random effects model should be conducted.
level	The level used to calculate confidence intervals for combinations of components.
nchar.comps	A numeric defining the minimum number of characters used to create unique names for components (see Details).
backtransf	A logical indicating whether printed results should be back transformed. If backtransf=TRUE, results for sm="OR" are printed as odds ratios rather than log odds ratios.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).

<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .
<code>digits.stat</code>	Minimal number of significant digits for z-value of test for overall effect, see <code>print.default</code> .
<code>digits.pval</code>	Minimal number of significant digits for p-values, see <code>print.default</code> .
<code>scientific.pval</code>	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
<code>zero.pval</code>	A logical specifying whether p-values should be printed with a leading zero.
<code>JAMA.pval</code>	A logical specifying whether p-values for test of combination effect should be printed according to JAMA reporting standards.
<code>big.mark</code>	A character used as thousands separator.
<code>legend</code>	A logical indicating whether a legend should be printed.

Details

R functions `netcomb` and `discomb` only report results for complex interventions present in the network. This function can be used to calculate the effect for arbitrary complex interventions.

Complex interventions can be specified using argument `complex`:

- a character vector with definition of complex interventions,
- a single numeric defining the number of components to combine in a complex intervention,
- a dedicated C matrix.

In order to calculate effects of arbitrary complex interventions, a C matrix is needed which describes how the complex interventions are composed by the components (Rücker et al., 2020, Section 3.2). The C matrix is constructed internally if not provided by argument `complex`. All complex interventions occurring in the network are considered if argument `complex` is missing.

By default, component names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.comps` can be used to define the minimum number of characters for abbreviated component names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated component names.

Value

A list is returned by the function `netcomplex` with the following elements:

<code>complex</code>	Complex intervention(s).
<code>Comb.common</code> , <code>Comb.random</code>	A vector of combination effects (common and random effects model).
<code>seComb.common</code> , <code>seComb.random</code>	A vector with corresponding standard errors (common and random effects model).
<code>lower.Comb.common</code> , <code>lower.Comb.random</code>	A vector with lower confidence limits for combinations (common and random effects model).
<code>upper.Comb.common</code> , <code>upper.Comb.random</code>	A vector with upper confidence limits for combinations (common and random effects model).

```

statistic.Comb.common, statistic.Comb.random
    A vector with z-values for the overall effect of combinations (common and random effects model).
pval.Comb.common, pval.Comb.random
    A vector with p-values for the overall effect of combinations (common and random effects model).
common, random
    A defined above.
level, nchar.comps, backtransf, x
    A defined above.
C.matrix
    C matrix.

```

Note

R function [netcomparison](#) can be used to calculate the effect for comparisons of two arbitrary complex intervention in a component network meta-analysis.

netconnection.default *Get information on network connectivity (number of subnetworks, distance matrix)*

Description

To determine the network structure and to test whether a given network is fully connected. Network information is provided as a triple of vectors `treat1`, `treat2`, and `studlab` where each row corresponds to an existing pairwise treatment comparison (`treat1`, `treat2`) in a study (`studlab`). The function calculates the number of subnetworks (connectivity components; value of 1 corresponds to a fully connected network) and the distance matrix (in block-diagonal form in the case of subnetworks). If some treatments are combinations of other treatments or have common components, an analysis based on the additive network meta-analysis model might be possible, see [discomb](#) function.

Usage

```
## Default S3 method:
```

```
netconnection(  
  data = NULL,  
  treat1,  
  treat2,  
  studlab = NULL,  
  subset = NULL,  
  sep.trts = ":",  
  nchar.trts = 666,  
  title = "",  
  details.disconnected = FALSE,  
  warn = FALSE,  
  ...  
)  
  
## S3 method for class 'pairwise'  
netconnection(  
  data,  
  treat1,  
  treat2,  
  studlab = NULL,  
  subset = NULL,  
  sep.trts = ":",  
  drop.NA = TRUE,  
  nchar.trts = 666,  
  title = "",  
  details.disconnected = FALSE,  
  warn = FALSE,  
  ...  
)  
  
## S3 method for class 'netmeta'  
netconnection(  
  data,  
  sep.trts = data$sep.trts,  
  nchar.trts = data$nchar.trts,  
  title = data$title,  
  details.disconnected = FALSE,  
  warn = FALSE,  
  ...  
)  
  
## S3 method for class 'netcomb'  
netconnection(  
  data,  
  sep.trts = data$sep.trts,  
  nchar.trts,  
  title = data$title,  
  details.disconnected = FALSE,
```

```

    warn = FALSE,
    ...
)

## S3 method for class 'netconnection'
print(
  x,
  digits = max(4, .Options$digits - 3),
  nchar.trts = x$nchar.trts,
  details = FALSE,
  details.disconnected = x$details.disconnected,
  ...
)

netconnection(data, ...)

```

Arguments

data	A data frame, e.g., created with pairwise .
treat1	Label / number for first treatment (ignored if data was created with pairwise).
treat2	Label / number for second treatment (ignored if data was created with pairwise).
studlab	Study labels (ignored if data was created with pairwise).
subset	An optional vector specifying a subset of studies to be used.
sep.trts	A character used in comparison names as separator between treatment labels.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
title	Title of meta-analysis / systematic review.
details.disconnected	A logical indicating whether to print more details for disconnected networks.
warn	A logical indicating whether warnings should be printed.
...	Additional arguments (ignored at the moment)
drop.NA	A logical indicating whether comparisons with missing treatment estimates or standard errors should be considered.
x	An object of class netconnection.
digits	Minimal number of significant digits, see print.default .
details	A logical indicating whether to print the distance matrix.

Value

An object of class netconnection with corresponding print function. The object is a list containing the following components:

treat1, treat2, studlab, title, warn, nchar.trts	As defined above.
k	Total number of studies.

m	Total number of pairwise comparisons.
n	Total number of treatments.
n.subnets	Number of subnetworks; equal to 1 for a fully connected network.
D.matrix	Distance matrix.
A.matrix	Adjacency matrix.
L.matrix	Laplace matrix.
call	Function call.
version	Version of R package netmeta used to create object.

netcontrib

Contribution matrix in network meta-analysis

Description

This function generates the contribution of direct comparisons to every network treatment comparison. The output is a matrix where rows represent network treatment effects and columns represent the contribution of direct treatment effects.

Usage

```

netcontrib(
  x,
  method = "shortestpath",
  hatmatrix.F1000 = FALSE,
  common = x$common,
  random = x$random,
  nchar.trts = x$nchar.trts,
  warn.deprecated = gs("warn.deprecated"),
  verbose = FALSE,
  ...
)

## S3 method for class 'netcontrib'
print(
  x,
  common = x$x$common,
  random = x$x$random,
  digits = 4,

```

```
nchar.trts = x$nchar.trts,
legend = gs("legend"),
warn.deprecated = gs("warn.deprecated"),
...
)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> or <code>netcontrib</code> .
<code>method</code>	A character string indicating which method is to calculate the contribution matrix. Either <code>"randomwalk"</code> , <code>"shortestpath"</code> , <code>"cccp"</code> , or <code>"pseudoinverse"</code> , can be abbreviated.
<code>hatmatrix.F1000</code>	A logical indicating whether hat matrix given in F1000 article should be used for <code>method = "shortestpath"</code> .
<code>common</code>	A logical indicating whether a contribution matrix should be printed for the common effects network meta-analysis.
<code>random</code>	A logical indicating whether a contribution matrix should be printed for the random effects network meta-analysis.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names (see <code>Details</code>).
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>verbose</code>	A logical indicating whether progress information should be printed.
<code>...</code>	Additional arguments.
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .
<code>legend</code>	A logical indicating whether a legend should be printed.

Details

In network meta-analysis (NMA), it is important to assess the influence of limitations or other characteristics of individual studies on the estimates obtained from the network. To this end, the contribution matrix shows how much each direct treatment effect contributes to each treatment effect estimate from network meta-analysis.

We use ideas from graph theory to derive the proportion that is contributed by each direct treatment effect using R package **igraph**. We start with the 'projection' matrix in a two-step network meta-analysis model, called the H matrix, which is analogous to the hat matrix in a linear regression model. H entries are translated to proportion contributions based on the observation that the rows of H can be interpreted as flow networks. A stream is defined as the composition of a path and its associated flow (Papakonstantinou et al., 2018).

To account for multi-arm trials, we use the H matrix from a two-step (aggregate) version of the graph theoretical NMA model (Davies et al., 2022). This H matrix can be obtained from `hatmatrix` with argument `method = "davies"`.

Four methods are implemented to estimate the proportion contributions:

(1) If argument `method = "randomwalk"`, an analytical random-walk (RW) approach is used (Davies et al., 2022). Here, the "full" version of the aggregate H matrix (`hatmatrix` with arguments `method = "davies"` and `type = "full"`) is used to define RW transition matrices. For each pair of treatments (ij) in the network, the elements in the corresponding row of H-full define a transition matrix from node i to node j. We use the **igraph** package to find every (directed) path from node i to node j. The flow through each path is then equal to the probability that a walker takes that path. This is simply the product of the transition probabilities associated with each edge along the path.

(2) If argument `method = "shortestpath"`, an iterative algorithm is used (Papakonstantinou et al., 2018). Broadly speaking, each iteration of the algorithm consists of the following steps: (i) A path in the evidence flow network is selected. (ii) The minimum flow through the edges making up the path is identified. This is assigned as the flow associated with the path. (iii) The flow of the path is subtracted from the values of flow in the edges that make up that path. This means that the edge corresponding to the minimum flow in that path is removed from the graph. (iv) A new path is then selected from the remaining graph. The process repeats until all the evidence flow in the edges has been assigned to a path.

In the original F1000 paper (Papakonstantinou et al., 2018), the hat matrix used did not account for correlations due to multi-arm trials. For reproducibility the result of this version can be obtained by specifying `hatmatrix.F1000 = TRUE` for `method = "shortestpath"`. For other purposes, this method is not recommended.

(3) If argument `method = "cccp"`, contributions are estimated using [l1](#) from R package **cccp** which must be available (Rücker et al., 2024).

(4) If argument `method = "pseudoinverse"`, contributions are derived from an L2 solution based on a Moore-Penrose pseudoinverse (Rücker et al., 2024).

Once the streams have been identified by any method, the proportion contribution of each direct comparison is equal to the sum over the flow of evidence in each path containing that edge divided by the number of edges that make up that path.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.trts` can be used to define the minimum number of characters for abbreviated treatment names (see [abbreviate](#), argument `minlength`). R function `treats` is utilised internally to create abbreviated treatment names.

Calculation of network contributions can be compute-intensive for the random-walk approach in large networks. Crude information on the computation progress is printed if argument `verbose` is `TRUE`. In addition, computation times are printed if R package **tictoc** is installed.

Value

An object of class `netcontrib` with corresponding print function. The object is a list containing the following components:

<code>common</code>	Numeric matrix of percentage contributions of direct comparisons for each network comparison for the common effects model.
<code>random</code>	Numeric matrix of percentage contributions of direct comparisons for each network comparison for the random effects model.
<code>x</code>	As defined above.
<code>tictoc.common</code>	Computation times under common effects model (if R package tictoc is installed).

`tictoc.random` Computation times under random effects model (if R package **tictoc** is installed).

with the contribution matrices for common and random NMA. Each matrix has the percentage contributions of each direct comparison as columns for each network comparison, direct or indirect as rows.

netdistance.default *Calculate distance matrix for an adjacency matrix*

Description

Calculate distance matrix for an adjacency matrix based on distance algorithm by Müller et al. (1987).

Usage

```
## Default S3 method:
netdistance(x, ...)

## S3 method for class 'netmeta'
netdistance(x, sort = gs("sort.distance"), ...)

## S3 method for class 'netcomb'
netdistance(x, sort = gs("sort.distance"), ...)

## S3 method for class 'netconnection'
netdistance(x, ...)

## S3 method for class 'netdistance'
print(x, lab.Inf = ".", ...)

netdistance(x, ...)
```

Arguments

x	Either a netmeta or netcomb object or an adjacency matrix.
...	Additional arguments.
sort	A logical indicating whether to sort within (sub)networks by treatment names.
lab.Inf	A character string to label infinite values.

# Examples: example(netgraph.netmeta)
```

netgraph.discomb *Network graph for objects of class discomb*

Description

This function generates a graph of the evidence network.

Usage

```
## S3 method for class 'discomb'
netgraph(
  x,
  labels = x$trts,
  adj = NULL,
  offset = if (!is.null(adj) && all(unique(adj) == 0.5)) 0 else 0.0175,
  rotate = 0,
  points = !missing(cex.points),
  cex.points = 1,
  ...
)
```

Arguments

x	An object of class <code>discomb</code> .
labels	An optional vector with treatment labels.
adj	One, two, or three values in $[0, 1]$ (or a vector / matrix with length / number of rows equal to the number of treatments) specifying the x (and optionally y and z) adjustment for treatment labels.
offset	Distance between edges (i.e. treatments) in graph and treatment labels for 2-D plots (value of 0.0175 corresponds to a difference of 1.75% of the range on x- and y-axis).
rotate	A single numeric with value between -180 and 180 specifying the angle to rotate nodes in a circular network.
points	A logical indicating whether points should be printed at nodes (i.e. treatments) of the network graph.
cex.points	Corresponding point size. Can be a vector with length equal to the number of treatments.
...	Additional arguments passed on to netgraph.netmeta .

Details

The arguments `seq` and `iterate` are used internally and cannot be specified by the user.

netgraph.netconnection

Network graph for objects of class netconnection

Description

This function generates a graph of the evidence network.

Usage

```
## S3 method for class 'netconnection'
netgraph(
  x,
  seq,
  col = seq_len(x$n.subnets),
  reference.group = NULL,
  plastic = gs("plastic"),
  ...
)
```

Arguments

<code>x</code>	An object of class <code>netconnection</code> .
<code>seq</code>	A character or numerical vector specifying the sequence of treatments arrangement (anticlockwise if <code>start.layout = "circle"</code>).
<code>col</code>	A single color (or vector of colors) for lines connecting treatments (edges) if argument <code>plastic = FALSE</code> (see Details).
<code>reference.group</code>	Reference treatment (only relevant for disconnected networks).
<code>plastic</code>	A logical indicating whether the appearance of the comparisons should be in '3D look'.
<code>...</code>	Additional arguments passed on to <code>netgraph.netmeta</code> (see Details).

Details

Argument `col` can be a single color for all edges, a vector of length equal to the number of edges, or a vector of length equal to the number of subnetworks. Argument `reference.group` is only considered in disconnected networks, i.e., if more than one (sub)network exists, and if argument `col` provides colors for subnetworks. In this case, the first color provided in argument `col` defines the color for the subnetwork with the reference treatment.

netgraph.netimpact *Network graph for objects of class netimpact*

Description

This function generates a graph of the evidence network.

Usage

```
## S3 method for class 'netimpact'
netgraph(
  x,
  col.ignore = "red",
  number.of.studies = TRUE,
  main,
  sub,
  multiarm = gs("multiarm"),
  col.multiarm = NULL,
  alpha.transparency = 0.5,
  col.ignore.multiarm = "transparent",
  col = "black",
  plastic = gs("plastic"),
  ...
)
```

Arguments

<code>x</code>	An object of class <code>netimpact</code> .
<code>col.ignore</code>	A character string indicating color for comparisons removed from network, either "transparent" or any color defined in colours .
<code>number.of.studies</code>	A logical indicating whether number of studies should be added to network graph.
<code>main</code>	Main title.
<code>sub</code>	Subtitle.
<code>multiarm</code>	A logical indicating whether multi-arm studies should be marked in plot.
<code>col.multiarm</code>	Either a function from R package colorspace or grDevice to define colors for multi-arm studies or a character vector with colors to highlight multi-arm studies.

alpha.transparency	The alpha transparency of colors used to highlight multi-arm studies (0 means transparent and 1 means opaque).
col.ignore.multiarm	A character string indicating color to mark multi-arm studies removed from network, either "transparent" or any color defined in colours .
col	A single color (or vector of colors) for lines connecting treatments (edges) if argument plastic = FALSE. Length of the vector must be equal to the number of edges.
plastic	A logical indicating whether the appearance of the comparisons should be in '3D look'.
...	Additional arguments passed on to netgraph.netmeta .

    ...
)

```

Arguments

x	An object of class netmeta (mandatory).
seq	A character or numerical vector specifying the sequence of treatments arrange-

	ment (anticlockwise if <code>start.layout = "circle"</code>).
<code>labels</code>	An optional vector with treatment labels.
<code>cex</code>	The magnification to be used for treatment labels.
<code>adj</code>	One, two, or three values in $[0, 1]$ (or a vector / matrix with length / number of rows equal to the number of treatments) specifying the x (and optionally y and z) adjustment for treatment labels.
<code>srt.labels</code>	The character string "orthogonal" (can be abbreviated), a single numeric or numerical vector with value(s) between -180 and 180 specifying the angle to rotate treatment labels (see Details).
<code>offset</code>	Distance between edges (i.e. treatments) in graph and treatment labels for 2-D plots (value of 0.0175 corresponds to a difference of 1.75% of the range on x- and y-axis).
<code>scale</code>	Additional space added outside of edges (i.e. treatments). Increase this value for larger treatment labels (value of 1.10 corresponds to an additional space of 10% around the network graph).
<code>col</code>	A single color (or vector of colors) for lines connecting treatments (edges) if argument <code>plastic = FALSE</code> . Length of the vector must be equal to the number of edges (see list element 'comparisons' in <code>netmeta</code>).
<code>plastic</code>	A logical indicating whether the appearance of the comparisons should be in '3D look' (not to be confused with argument <code>dim</code>).
<code>thickness</code>	Either a character variable to determine the method to plot line widths (see Details) or a matrix of the same dimension and row and column names as argument <code>A.matrix</code> with information on line width.
<code>lwd</code>	A numeric for scaling the line width of comparisons.
<code>lwd.min</code>	Minimum line width in network graph. All connections with line widths below this values will be set to <code>lwd.min</code> .
<code>lwd.max</code>	Maximum line width in network graph. The connection with the largest value according to argument <code>thickness</code> will be set to this value.
<code>rescale.thickness</code>	A logical value or R function to scale the thickness of lines (see Details).
<code>dim</code>	A character string indicating whether a 2- or 3-dimensional plot should be produced, either "2d" or "3d".
<code>rotate</code>	A single numeric with value between -180 and 180 specifying the angle to rotate nodes in a circular network.
<code>highlight</code>	A character vector identifying comparisons that should be marked in the network graph, e.g. <code>highlight = "treat1:treat2"</code> .
<code>col.highlight</code>	Color(s) to highlight the comparisons given by <code>highlight</code> .
<code>scale.highlight</code>	Scaling factor(s) for the line width(s) to highlight the comparisons given by <code>highlight</code> .
<code>multiarm</code>	A logical indicating whether multi-arm studies should be marked in plot.
<code>col.multiarm</code>	Either a function from R package colorspace or grDevice to define colors for multi-arm studies or a character vector with colors to highlight multi-arm studies.

<code>alpha.transparency</code>	The alpha transparency of colors used to highlight multi-arm studies (0 means transparent and 1 means opaque).
<code>points</code>	A logical indicating whether points should be printed at nodes (i.e. treatments) of the network graph.
<code>cex.points</code> , <code>pch.points</code> , <code>col.points</code> , <code>bg.points</code>	Corresponding size, type, color, and background color for points. Can be a vector with length equal to the number of treatments.
<code>points.min</code>	Minimum point size. All points with size below this values will be set to <code>points.min</code> .
<code>points.max</code>	Maximum point size in network graph. The node with the largest value according to argument <code>cex.points</code> will be set to this value.
<code>rescale.pointsize</code>	A logical value or R function to scale the point size (see Details).
<code>number.of.studies</code>	A logical indicating whether number of studies should be added to network graph.
<code>cex.number.of.studies</code>	The magnification to be used for number of studies.
<code>col.number.of.studies</code>	Color for number of studies.
<code>bg.number.of.studies</code>	Color for shadow around number of studies.
<code>pos.number.of.studies</code>	A single value (or vector of values) in $[0, 1]$ specifying the position of the number of studies on the lines connecting treatments (edges). Length of the vector must be equal to the number of edges.
<code>start.layout</code>	A character string indicating which starting layout is used if <code>iterate = TRUE</code> . If "circle" (default), the iteration starts with a circular ordering of the vertices; if "eigen", eigenvectors of the Laplacian matrix are used, calculated via generic function <code>eigen</code> (spectral decomposition); if "prcomp", eigenvectors of the Laplacian matrix are calculated via generic function <code>prcomp</code> (principal component analysis); if "random", a random layout is used, drawn from a bivariate normal.
<code>eig1</code>	A numeric indicating which eigenvector is used as x coordinate if <code>start = "eigen"</code> or <code>"prcomp"</code> and <code>iterate = TRUE</code> . Default is 2, the eigenvector to the second-smallest eigenvalue of the Laplacian matrix.
<code>eig2</code>	A numeric indicating which eigenvector is used as y-coordinate if <code>start = "eigen"</code> or <code>"prcomp"</code> and <code>iterate = TRUE</code> . Default is 3, the eigenvector to the third-smallest eigenvalue of the Laplacian matrix.
<code>eig3</code>	A numeric indicating which eigenvector is used as z-coordinate if <code>start = "eigen"</code> or <code>"prcomp"</code> and <code>iterate = TRUE</code> . Default is 4, the eigenvector to the fourth-smallest eigenvalue of the Laplacian matrix.
<code>iterate</code>	A logical indicating whether the stress majorization algorithm is carried out for optimization of the layout.
<code>tol</code>	A numeric for the tolerance for convergence if <code>iterate = TRUE</code> .

maxit	An integer defining the maximum number of iteration steps if <code>iterate = TRUE</code> .
allfigures	A logical indicating whether all iteration steps are shown if <code>iterate = TRUE</code> . May slow down computations if set to <code>TRUE</code> (especially if <code>plastic = TRUE</code>).
A.matrix	Adjacency matrix (nxn) characterizing the structure of the network graph. Row and column names must be the same set of values as provided by argument <code>seq</code> .
N.matrix	Neighborhood matrix (nxn) replacing A.matrix if <code>neighborhood</code> is to be specified differently from node adjacency in the network graph, for example content-based. Row and column names must be the same set of values as provided by argument <code>seq</code> .
D.matrix	Distance matrix (nxn) replacing A.matrix and N.matrix if distances should be provided directly. Row and column names must be the same set of values as provided by argument <code>seq</code> .
xpos	Vector (n) of x coordinates.
ypos	Vector (n) of y coordinates.
zpos	Vector (n) of z coordinates.
figure	A logical indicating whether network graph should be shown.
...	Additional graphical arguments (passed on to <code>plot.default</code>).

Details

This function generates a network graph for an R object created with `netmeta`. R function `plot.default` is used to create the network graph.

Layout of network graph: The network is laid out in the plane, where the nodes in the graph layout correspond to the treatments and edges display the observed treatment comparisons. For the default setting, nodes are placed on a circle. Other starting layouts are "eigen", "prcomp", and "random" (Rücker & Schwarzer 2015). If `iterate = TRUE`, the layout is further optimized using the stress majorization algorithm. This algorithm specifies an 'ideal' distance (e.g., the graph distance) between two nodes in the plane. In the optimal layout, these distances are best approximated in the sense of least squares. Starting from an initial layout, the optimum is approximated in an iterative process called stress majorization (Kamada and Kawai 1989, Michailidis and de Leeuw 2001, Hu 2012). The starting layout can be chosen as a circle or coming from eigenvectors of the Laplacian matrix (corresponding to Hall's algorithm, Hall 1970), calculated in different ways, or random. Moreover, it can be chosen whether the iteration steps are shown (argument `allfigures = TRUE`).

An optimized circular presentation which typically has a reduced (sometimes minimal) number of crossings can be achieved by using argument `seq = "optimal"` in combination with argument `start.layout`. Note, it is not possible to prespecify the best value for argument `start.layout` for any situation as the result depends on the network structure.

Definition of line widths: Argument `thickness` providing the line width of edges (comparisons) can be a matrix of the same dimension as argument `A.matrix` or any of the following character strings (which can be abbreviated):

- Proportional to number of studies comparing two treatments (`thickness = "number.of.studies", default`)

- Proportional to inverse standard error of common effects model comparing two treatments (thickness = "se.common")
- Proportional to inverse standard error of random effects model comparing two treatments (thickness = "se.random")
- Weight from common effects model comparing two treatments (thickness = "w.common")
- Weight from random effects model comparing two treatments (thickness = "w.random")
- Same line width for all comparisons (thickness = "equal")

Only evidence from direct treatment comparisons is considered to determine the line width if argument thickness is equal to any but the last method.

Line widths are determined by argument lwd if all lines have the same width. This is possible if either argument thickness = "equal", all pairwise comparisons have the same number of studies for thickness = "number.of.studies" or all direct comparisons are equally precise.

Otherwise, the line width of the thickest line is equal to the value of argument lwd.max and all lines with a thickness below the value of argument lwd.min are set to this value. Default for argument lwd.max is $4 * lwd$.

Argument rescale.thickness can be used to provide a function to specify the relative line width of edges (comparisons). By default, the square root function `sqrt` is used in order to lessen differences in line widths. Argument rescale.thickness = FALSE or rescale.thickness = I, i.e., the identity function `I`, can be used to not rescale line widths.

Definition of point sizes: Points are printed at nodes (treatments) if argument points = TRUE or argument cex.points is provided.

Point sizes are equal to the value of argument cex.points if all points are of equal size.

Otherwise, the point size of the largest point is equal to the value of argument points.max and all points smaller than the value of argument points.min are set to this value. The default for argument points.max is equal to the largest value provided in argument cex.points if this largest value is below or equal to 25. Otherwise the default is points.max = 8.

Argument rescale.pointsize can be used to provide a function to specify relative point sizes. Point sizes are not rescaled at all if they are all equal or the largest cex.points value is below or equal to 25. Otherwise, the square root function `sqrt` is used in order to lessen the differences in point sizes. Argument rescale.pointsize = FALSE or rescale.pointsize = I, i.e., the identity function `I`, can be used to not rescale point sizes.

Other settings: Argument srt.labels can be used to specify the rotation (in degrees) of the treatment labels. If srt.labels is equal to "orthogonal", treatment labels are orthogonal to the circle. If srt.labels is a single numeric, all labels are rotated by this degree. If srt.labels is a numeric vector, it must be of the same length as the number of treatments and labels are rotated counter-clockwise starting on the right side. Finally, if srt.labels is a named numeric vector, it must be of the same length as the number of treatments and the names must be equal to the treatment names (and treatment labels are rotated according to the specified values).

Further, a couple of graphical parameters can be specified, such as color and appearance of the edges (treatments) and the nodes (comparisons), whether special comparisons should be highlighted and whether multi-arm studies should be indicated as colored polygons. By default, the `sequential_hcl` function is used to highlight multi-arm studies.

In order to generate 3-D plots (argument dim = "3d"), R package `rgl` is necessary. Note, under macOS the X.Org X Window System must be available (see <https://www.xquartz.org>).

Value

A list containing two data frames with information on nodes and edges.

List element 'nodes'

trts	Treatment names.
labels	Treatment labels.
seq	Sequence of treatment labels.
srt	String rotation.
xpos	Position of treatment / edge on x-axis.
ypos	Position of treatment / edge on y-axis.
zpos	Position of treatment / edge on z-axis (for 3-D plots).
xpos.labels	Position of treatment labels on x-axis (for 2-D plots).
ypos.labels	Position of treatment labels on y-axis (for 2-D plots).
offset.x	Offset of treatment labels on x-axis (for 2-D plots).
offset.y	Offset of treatment labels on y-axis (for 2-D plots).
cex	Point size of treatments / edges.
col	Color for points.
pch	Point type.
bg	Background color for points.
adj.x	Adjustment for treatment label on x-axis.
adj.y	Adjustment for treatment label on y-axis.
adj.z	Adjustment for treatment label on z-axis (for 3-D plots).

List element 'edges'

treat1	Name of first treatment.
treat2	Name of second treatment.
n.stud	Number of studies directly comparing treatments.
xpos	Position of number of studies on x-axis.
ypos	Position of number of studies on y-axis.
adj	Adjustment of number of studies.
pos.number.of.studies	Position of number of studies on edge.
col	Color for edges.

netheat

Net heat plot

Description

This function creates a net heat plot, a graphical tool for locating inconsistency in network meta-analyses.

Usage

```

netheat(
  x,
  random = FALSE,
  tau.preset = NULL,
  showall = TRUE,
  nchar.trts = x$nchar.trts,
  ...
)

```

Arguments

x	An object of class netmeta.
random	A logical indicating whether the net heat plot should be based on a random effects model.
tau.preset	An optional value for the square-root of the between-study variance τ^2 for a random effects model on which the net heat plot will be based.
showall	A logical indicating whether results should be shown for all designs or only a sensible subset (see Details).
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
...	Additional arguments.

Details

The net heat plot is a matrix visualization proposed by Krahn et al. (2013) that highlights hot spots of inconsistency between specific direct evidence in the whole network and renders transparent possible drivers.

In this plot, the area of a gray square displays the contribution of the direct estimate of one design in the column to a network estimate in a row. In combination, the colors show the detailed change in inconsistency when relaxing the assumption of consistency for the effects of single designs. The colors on the diagonal represent the inconsistency contribution of the corresponding design. The colors on the off-diagonal are associated with the change in inconsistency between direct and indirect evidence in a network estimate in the row after relaxing the consistency assumption for the effect of one design in the column. Cool colors indicate an increase and warm colors a decrease: the stronger the intensity of the color, the greater the difference between the inconsistency before and after the detachment. So, a blue colored element indicates that the evidence of the design in the column supports the evidence in the row. A clustering procedure is applied to the heat matrix in order to find warm colored hot spots of inconsistency. In the case that the colors of a column corresponding to design d are identical to the colors on the diagonal, the detaching of the effect of design d dissolves the total inconsistency in the network.

The pairwise contrasts corresponding to designs of three- or multi-arm studies are marked by ' _ ' following the treatments of the design.

Designs where only one treatment is involved in other designs of the network or where the removal of corresponding studies would lead to a splitting of the network do not contribute to the inconsistency assessment. By default (`showall = TRUE`), these designs are not incorporated into the net heat plot. If `showall = FALSE`, additional designs with minimal contribution to the inconsistency Q statistic are not incorporated (i.e., designs with $\text{abs}(Q.\text{inc.design}) \leq .\text{Machine}\$double.\text{eps}^{\wedge}0.5$).

In the case of `random = TRUE`, the net heat plot is based on a random effects model generalised for multivariate meta-analysis in which the between-study variance τ^2 is estimated by the method of moments (see Jackson et al., 2012) and embedded in a full design-by-treatment interaction model (see Higgins et al., 2012).

netimpact

Determine the importance of individual studies in network meta-analysis

Description

This function measures the importance of individual studies in network meta-analysis by the reduction of the precision if the study is removed / ignored from the network (Rücker et al., 2020).

Usage

```

netimpact(
  x,
  seTE.ignore = 100 * max(x$seTE, na.rm = TRUE),
  event.ignore = 0.01,
  nchar.trts = x$nchar.trts,
  nchar.studlab = x$nchar.studlab,
  verbose = FALSE
)

```

Arguments

x	An object of class netmeta.
seTE.ignore	Assumed (large) standard error in order to mimicking the removal of individual studies from the network meta-analysis (ignored for <code>netmetabin</code> objects).
event.ignore	Assumed event number mimicking the removal of individual studies from the network meta-analysis (considered for <code>netmetabin</code> objects).
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names (see Details).
nchar.studlab	A numeric defining the minimum number of characters used to create unique study labels.
verbose	A logical indicating whether information on the estimation progress should be printed.

Value

An object of class "netimpact" with corresponding netgraph and print function. The object is a list containing the following components:

impact.common	A matrix with contributions of individual studies (columns) to comparisons (rows) under the common effects model.
impact.random	A matrix with contributions of individual studies (columns) to comparisons (rows) under the random effects model.
ignored.comparisons	List with comparisons of ignored study.
seTE.ignore, event.ignore, x	As defined above.
nets	List of all network meta-analyses (removing a single study).
version	Version of R package netmeta used to create object.

netleague

Create league table with network meta-analysis results

Description

A league table is a square matrix showing all pairwise comparisons in a network meta-analysis. Typically, both treatment estimates and confidence intervals are shown.

Usage

```

netleague(
  x,
  y,
  common = x$common,
  random = x$random,
  seq = x$seq,
  ci = TRUE,
  backtransf = x$backtransf,

```

```

direct,
digits = gs("digits"),
big.mark = gs("big.mark"),
text.NA = ".",
bracket = gs("CIBracket"),
separator = gs("CIseparator"),
lower.blank = gs("CIlower.blank"),
upper.blank = gs("CIupper.blank"),
writexl = !missing(path),
path = "leaguetable.xlsx",
overwrite = FALSE,
details = gs("details"),
warn.deprecated = gs("warn.deprecated"),
...
)

## S3 method for class 'netleague'
print(
  x,
  common = x$x$common,
  random = x$x$random,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

```

Arguments

x	An object of created with netmeta, netcomb, discomb, or netleague (mandatory).
y	An object of class netmeta, netcomb, or discomb (optional).
common	A logical indicating whether a league table should be printed for the common effects network meta-analysis.
random	A logical indicating whether a league table should be printed for the random effects network meta-analysis.
seq	A character or numerical vector specifying the sequence of treatments in rows and columns of a league table.
ci	A logical indicating whether confidence intervals should be shown.
backtransf	A logical indicating whether printed results should be back transformed. If backtransf = TRUE, results for sm = "OR" are printed as odds ratios rather than log odds ratios, for example.
direct	A logical indicating whether league tables with network estimates or estimates from direct comparisons should be shown if (i) argument y is provided and the input for arguments x and y was created with netmeta or (ii) input for argument x was created with netmeta or netcomb.
digits	Minimal number of significant digits, see print.default.
big.mark	A character used as thousands separator.

<code>text.NA</code>	A character string to label missing values.
<code>bracket</code>	A character with bracket symbol to print lower confidence interval: "[", "(", "{", "".
<code>separator</code>	A character string with information on separator between lower and upper confidence interval.
<code>lower.blank</code>	A logical indicating whether blanks between left bracket and lower confidence limit should be printed.
<code>upper.blank</code>	A logical indicating whether blanks between separator and upper confidence limit should be printed.
<code>writexl</code>	A logical indicating whether an Excel file should be created (R package writexl must be available).
<code>path</code>	A character string specifying the filename of the Excel file.
<code>overwrite</code>	A logical indicating whether an existing Excel file should be overwritten.
<code>details</code>	A logical specifying whether details on rows and columns should be printed.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments (passed on to <code>write_xlsx</code> to create Excel file).

Details

A league table is a square matrix showing all pairwise comparisons in a network meta-analysis (Hutton et al., 2015). Typically, both treatment estimates and confidence intervals are shown.

If argument `y` is not provided, the league table contains

- the network estimates in the lower triangle and the direct treatment estimates from pairwise comparisons in the upper triangle, if the input for argument `x` was created with `netmeta`;
- the network estimates from the component network meta-analysis in the lower triangle, if the input for argument `x` was created with `netcomb`, and, in the upper triangle, (i) the network estimates from the network meta-analysis, if argument `direct = FALSE`, or (ii) the direct treatment estimates from pairwise comparisons, if argument `direct = TRUE`;
- the network estimates from the component network meta-analysis in the lower and upper triangle, if the input for argument `x` was created with `discomb`.

Note, for the random-effects model, the direct treatment estimates are based on the common between-study variance τ^2 from the network meta-analysis, i.e. the square of list element `x$tau`.

If argument `y` is provided, the league table contains information on treatment comparisons from (component) network meta-analysis object `x` in the lower triangle and from (component) network meta-analysis object `y` in the upper triangle. This is, for example, useful to print information on efficacy and safety in the same league table. If argument `direct = TRUE`, direct estimates are shown both in the lower and upper triangle if the input for arguments `x` and `y` was created with `netmeta`.

By default, an R object with the league tables is generated. Alternatively, an Excel file is created if argument `writexl = TRUE`.

This implementation reports pairwise comparisons of the treatment in the column versus the treatment in the row in the lower triangle and row versus column in the upper triangle. This is a common

presentation for network meta-analyses which allows to easily compare direction and magnitude of treatment effects. For example, given treatments A, B, and C, the results reported in the first row and second column as well as second row and first column are from the pairwise comparison A versus B. Note, this presentation is different from the printout of a network meta-analysis object which reports opposite pairwise comparisons in the lower and upper triangle, e.g., A versus B in the first row and second column and B versus A in the second row and first column.

If the same (component) network meta-analysis object is used for arguments `x` and `y`, reciprocal treatment estimates will be shown in the upper triangle (see examples), e.g., the comparison B versus A.

R function `netrank` can be used to change the order of rows and columns in the league table (see examples).

Value

An object of class `netleague` with corresponding print function if `writexl = FALSE`. The object is a list containing the league tables in list elements `'common'` and `'random'`. An Excel file is created if `writexl = TRUE`. In this case, `NULL` is returned in R.

netmatrix

Create a matrix with additional information for pairwise comparisons

Description

Auxiliary function to create a matrix with additional information for pairwise comparisons

Usage

```

netmatrix(
  x,
  var,
  levels,
  labels = levels,
  func = "mode",
  ties.method = "random"
)

```

Arguments

x A [netmeta](#) object.

var Variable with additional information.

levels	An optional vector of the values that var might have taken (see factor).
labels	An optional vector with labels for var (see factor).
func	A character string with the function name to summarize values within pairwise comparisons; see Details .
ties.method	A character string describing how ties are handled if func = "mode"; see Details .

Details

For each pairwise comparison, unique values will be calculated for the variable var based on the argument func: "mode" (most common value), "min" (minimum value), "max", "mean", "median", and "sum". In order to determine the most common value, the argument ties.method can be used in the case of ties with "first" meaning that the first / smallest value will be selected; similar for "last" (last / largest value) and "random" (random selection).

Value

A matrix with the same row and column names as the adjacency matrix x\$A.matrix.

```

 netmeasures

Measures for characterizing a network meta-analysis

Description

This function provides measures for quantifying the direct evidence proportion, the mean path length and the minimal parallelism (the latter on aggregated and study level) of mixed treatment comparisons (network estimates) as well as the evidence flow per design, see König et al. (2013). These measures support the critical evaluation of the network meta-analysis results by rendering transparent the process of data pooling.

Usage

```
netmeasures(
  x,
  random = x$random | !missing(tau.preset),
  tau.preset = x$tau.preset,
  warn = gs("warn"),
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

x	An object of class netmeta.
random	A logical indicating whether random effects model should be used to calculate network measures.
tau.preset	An optional value for the square-root of the between-study variance τ^2 .
warn	A logical indicating whether warnings should be printed.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).

Details

The direct evidence proportion gives the absolute contribution of direct effect estimates combined for two-arm and multi-arm studies to one network estimate.

Concerning indirectness, comparisons with a mean path length beyond two should be interpreted with particular caution, as more than two direct comparisons have to be combined serially on average.

Large indices of parallelism, either on study-level or on aggregated level, can be considered as supporting the validity of a network meta-analysis if there is only a small amount of heterogeneity.

The network estimates for two treatments are linear combinations of direct effect estimates comparing these or other treatments. The linear coefficients can be seen as the generalization of weights known from classical meta-analysis. These coefficients are given in the projection matrix H of the underlying model. For multi-arm studies, the coefficients depend on the choice of the study-specific baseline treatment, but the absolute flow of evidence can be made explicit for each design as shown in König et al. (2013) and is given in `H.tilde`.

All measures are calculated based on the common effects meta-analysis by default. In the case that in function `netmeta` the argument `random = TRUE`, all measures are calculated for a random effects model. The value of the square-root of the between-study variance τ^2 can also be prespecified by argument `tau.preset` in function `netmeta`.

Value

A list containing the following components:

<code>random, tau.preset</code>	As defined above.
<code>proportion</code>	A named vector of the direct evidence proportion of each network estimate.
<code>meanpath</code>	A named vector of the mean path length of each network estimate.
<code>minpar</code>	A named vector of the minimal parallelism on aggregated level of each network estimate.
<code>minpar.study</code>	A named vector of the minimal parallelism on study level of each network estimate.
<code>H.tilde</code>	Design-based hat matrix with information on absolute evidence flow per design. The number of rows is equal to the number of possible pairwise treatment comparisons and the number of columns is equal to the number of designs.

netmeta

Network meta-analysis using graph-theoretical method

Description

Network meta-analysis is a generalisation of pairwise meta-analysis that compares all pairs of treatments within a number of treatments for the same condition. The graph-theoretical approach for network meta-analysis uses methods that were originally developed in electrical network theory. It has been found to be equivalent to the frequentist approach to network meta-analysis which is based on weighted least squares regression (Rücker, 2012). An extension for multi-arm studies with correlated treatment arms is also implemented (Rücker & Schwarzer, 2025, unpublished).

Usage

```

netmeta(
  TE,
  seTE,
  treat1,
  treat2,

title = gs("title"),
keepdata = gs("keepdata"),
keeprma = gs("keeprma"),
control = NULL,
warn = gs("warn"),
warn.deprecated = gs("warn.deprecated"),
nchar = nchar.trts,
...
)

```

Arguments

TE	Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio, mean difference, or log hazard ratio). Or an R object created with pairwise .
seTE	Standard error of treatment estimate.
treat1	Label/Number for first treatment.
treat2	Label/Number for second treatment.
studlab	An optional - but important! - vector with study labels (see Details).
data	An optional data frame containing the study information.
subset	An optional vector specifying a subset of studies to be used.

<code>correlated</code>	An optional logical vector specifying whether treatment arms of a multi-arm study are correlated (see Details).
<code>sm</code>	A character string indicating underlying summary measure, e.g., "RD", "RR", "OR", "ASD", "HR", "MD", "SMD", or "ROM".
<code>level</code>	The level used to calculate confidence intervals for individual comparisons.
<code>level.ma</code>	The level used to calculate confidence intervals for network estimates.
<code>common</code>	A logical indicating whether a common effects network meta-analysis should be conducted.
<code>random</code>	A logical indicating whether a random effects network meta-analysis should be conducted.
<code>prediction</code>	A logical indicating whether prediction intervals should be printed.
<code>level.predict</code>	The level used to calculate prediction intervals for a new study.
<code>reference.group</code>	Reference treatment (first treatment is used if argument is missing).
<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if <code>reference.group</code> has been specified.
<code>small.values</code>	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect (passed on to <code>netrank</code> , can be abbreviated).
<code>all.treatments</code>	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
<code>seq</code>	A character or numerical vector specifying the sequence of treatments in print-outs.
<code>method.tau</code>	A character string indicating which method is used to estimate the between-study variance τ^2 and its square root τ . Either "DL", "REML", or "ML", can be abbreviated.
<code>tau.preset</code>	An optional value for manually setting the square-root of the between-study variance τ^2 .
<code>tol.multiarm</code>	A numeric for the tolerance for consistency of treatment estimates in multi-arm studies which are consistent by design.
<code>tol.multiarm.se</code>	A numeric for the tolerance for consistency of standard errors in multi-arm studies which are consistent by design. This check is not conducted if the argument is NULL.
<code>details.chkmultiarm</code>	A logical indicating whether treatment estimates and / or variances of multi-arm studies with inconsistent results or negative multi-arm variances should be printed.
<code>sep.trts</code>	A character used in comparison names as separator between treatment labels.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names (see Details).

nchar.studlab	A numeric defining the minimum number of characters used to create unique study labels.
func.inverse	R function used to calculate the pseudoinverse of the Laplacian matrix L (see Details).
n1	Number of observations in first treatment group.
n2	Number of observations in second treatment group.
event1	Number of events in first treatment group.
event2	Number of events in second treatment group.
incr	Numerical value added to cell frequencies (for details, see pairwise).
mean1	Mean in first treatment group.
mean2	Mean in second treatment group.
sd1	Standard deviation in first treatment group.
sd2	Standard deviation in second treatment group.
time1	Person time at risk in first treatment group.
time2	Person time at risk in second treatment group.
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
title	Title of meta-analysis / systematic review.
keepdata	A logical indicating whether original data(set) should be kept in netmeta object.
keeprma	A logical indicating whether <code>rma.mv</code> object should be stored.
control	An optional list to control the iterative process to estimate the between-study variance τ^2 . This argument is passed on to <code>rma.mv</code> .
warn	A logical indicating whether warnings should be printed (e.g., if studies are excluded from meta-analysis due to zero standard errors).
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
nchar	Deprecated argument (replaced by <code>nchar.trts</code>).
...	Additional arguments (to catch deprecated arguments).

Details

Network meta-analysis using R package **netmeta** is described in detail in Schwarzer et al. (2015), Chapter 8.

Network meta-analysis model: Let n be the number of different treatments (nodes, vertices) in a network and let m be the number of existing comparisons (edges) between the treatments. If there are only two-arm studies, m is the number of studies. Let TE and seTE be the vectors of observed effects and their standard errors. Let W be the $m \times m$ diagonal matrix that contains the inverse variance $1 / \text{seTE}^2$.

The given comparisons define the network structure. Therefrom an $m \times n$ design matrix X (edge-vertex incidence matrix) is formed; for more precise information, see Rucker (2012). Moreover, the $n \times n$ Laplacian matrix L and its Moore-Penrose pseudoinverse L^+ are calculated (both matrices play an important role in graph theory and electrical network theory). Using these matrices, the variances based on both direct and indirect comparisons can be estimated. Moreover, the hat matrix H can be estimated by $H = XL + X^t W = X(X^t W X)^+ X^t W$ and finally consistent treatment effects can be estimated by applying the hat matrix to the observed (potentially inconsistent) effects. H is a projection matrix which maps the observed effects onto the consistent $(n-1)$ -dimensional subspace. This is the Aitken estimator (Senn et al., 2013). As in pairwise meta-analysis, the Q statistic measures the deviation from consistency. Q can be separated into parts for each pairwise meta-analysis and a part for remaining inconsistency between comparisons.

A simple random effects model assuming that a constant heterogeneity variance is added to each comparison of the network can be defined via a generalised method of moments estimate of the between-studies variance τ^2 (Jackson et al., 2012). This is added to the observed sampling variance $seTE^2$ of each comparison in the network (before appropriate adjustment for multi-arm studies). Then, as in standard pairwise meta-analysis, the procedure is repeated with the resulting enlarged standard errors.

For the random-effects model, the direct treatment estimates are based on the common between-study variance τ^2 from the network meta-analysis.

Multi-arm studies: Often multi-arm studies are included in a network meta-analysis. In multi-arm studies, the treatment effects on different comparisons are not independent, but correlated. This is accounted for by reweighting all comparisons of each multi-arm study. The method is described in Rucker (2012) and Rucker and Schwarzer (2014).

Comparisons belonging to multi-arm studies are identified by identical study labels (argument `studlab`). It is therefore important to use identical study labels for all comparisons belonging to the same multi-arm study, e.g., study label "Willms1999" for the three-arm study in the data example (Senn et al., 2013). The function `netmeta` then automatically accounts for within-study correlation by reweighting all comparisons of each multi-arm study.

Note, all pairwise comparisons must be provided for a multi-arm study. Consider a multi-arm study of p treatments with known variances. For this study, treatment effects and standard errors must be provided for each of $p(p-1)/2$ possible comparisons. For instance, a three-arm study contributes three pairwise comparisons, a four-arm study even six pairwise comparisons. Function `pairwise` automatically calculates all pairwise comparisons for multi-arm studies.

Studies with correlated treatment arms: The network meta-analysis method described in Rucker (2012) assumes that the treatment arms of a study are independent. This assumption is justified for parallel design trials and leads to variance consistency in multi-arm trials. However, this assumption is violated for trials with correlated arms, for example, split-body trials. For these trials, the variance of a contrast is not the sum of the arm-based variances, but comes with a correlation term which may lead to the violation of variance consistency. Using argument `correlated`, an alternative method is used for studies with correlated treatment arms (Rucker & Schwarzer, 2025, unpublished).

Argument `correlated`, which must be of the same length as arguments `TE`, `seTE`, etc., is a logical vector which must be `TRUE` for trials with correlated arms and `FALSE` otherwise. This can be easily done using a variable with design information like `correlated = design != "Parallel"`.

Data formats: Data entry for this function is in *contrast-based* format, that is, data are given as contrasts (differences) between two treatments (argument `TE`) with standard error (argument

seTE). In principle, meta-analysis functions from R package **meta**, e.g. `metabin` for binary outcomes or `metacont` for continuous outcomes, can be used to calculate treatment effects separately for each treatment comparison which is a rather tedious enterprise. If data are provided in *arm-based* format, that is, data are given for each treatment arm separately (e.g. number of events and participants for binary outcomes), a much more convenient way to transform data into contrast-based form is available. Function `pairwise` can automatically transform data with binary outcomes (using the `metabin` function from R package **meta**), continuous outcomes (`metacont` function), incidence rates (`metainc` function), and generic outcomes (`metagen` function). Additional arguments of these functions can be provided (see help page of function `pairwise`).

Additional comments: Internally, both common and random effects models are calculated regardless of values chosen for arguments `common` and `random`. Accordingly, the network estimates for the random effects model can be extracted from component `TE.random` of an object of class "netmeta" even if argument `random = FALSE`. However, all functions in R package **netmeta** will adequately consider the values for `common` and `random`. E.g. function `print.summary.netmeta` will not print results for the random effects model if `random = FALSE`.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.trts` can be used to define the minimum number of characters for abbreviated treatment names (see `abbreviate`, argument `minlength`). R function `treats` is utilised internally to create abbreviated treatment names.

Names of treatment comparisons are created by concatenating treatment labels of pairwise comparisons using `sep.trts` as separator (see `paste`). These comparison names are used in the covariance matrices `Cov.common` and `Cov.random` and in some R functions, e.g. `decomp.design`. By default, a colon is used as the separator. If any treatment label contains a colon the following characters are used as separator (in consecutive order): "-", "_", "/", "+", ".", "|", and "*". If all of these characters are used in treatment labels, a corresponding error message is printed asking the user to specify a different separator.

Value

An object of class `netmeta` with corresponding `print`, `summary`, `forest`, and `netrank` functions. The object is a list containing the following components:

<code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code>	As defined above.
<code>seTE.adj.common</code> , <code>seTE.adj.random</code>	Standard error of treatment estimate, adjusted for multi-arm studies.
<code>design</code>	Design of study providing pairwise comparison.
<code>n1</code> , <code>n2</code> , <code>event1</code> , <code>event2</code> , <code>incr</code>	As defined above.
<code>mean1</code> , <code>mean2</code> , <code>sd1</code> , <code>sd2</code> , <code>time1</code> , <code>time2</code>	As defined above.
<code>sd1</code> , <code>sd2</code> , <code>time1</code> , <code>time2</code>	As defined above.
<code>k</code>	Total number of studies.
<code>m</code>	Total number of pairwise comparisons.
<code>n</code>	Total number of treatments.

<code>d</code>	Total number of designs (corresponding to the unique set of treatments compared within studies).
<code>trts</code>	Treatments included in network meta-analysis.
<code>k.trts</code>	Number of studies evaluating a treatment.
<code>n.trts</code>	Number of observations receiving a treatment (if arguments <code>n1</code> and <code>n2</code> are provided).
<code>events.trts</code>	Number of events observed for a treatment (if arguments <code>event1</code> and <code>event2</code> are provided).
<code>multiarm</code>	Logical vector to identify pairwise comparisons from multi-arm studies.
<code>n.arms</code>	Number of treatment arms in study providing pairwise comparison.
<code>studies</code>	Vector with unique study labels.
<code>narms</code>	Number of arms for each study.
<code>designs</code>	Vector with unique designs present in the network. A design corresponds to the set of treatments compared within a study.
<code>comparisons</code>	Vector with unique direct comparisons present in the network.
<code>TE.nma.common</code> , <code>TE.nma.random</code>	A vector of length m of consistent treatment effects estimated by network meta-analysis (nma) (common / random effects model).
<code>seTE.nma.common</code> , <code>seTE.nma.random</code>	A vector of length m of effective standard errors estimated by network meta-analysis (common / random effects model).
<code>lower.nma.common</code> , <code>lower.nma.random</code>	A vector of length m of lower confidence interval limits for consistent treatment effects estimated by network meta-analysis (common effects / random effects model).
<code>upper.nma.common</code> , <code>upper.nma.random</code>	A vector of length m of upper confidence interval limits for the consistent treatment effects estimated by network meta-analysis (common effects / random effects model).
<code>statistic.nma.common</code> , <code>statistic.nma.random</code>	A vector of length m of z-values for test of treatment effect for individual comparisons (common / random effects model).
<code>pval.nma.common</code> , <code>pval.nma.random</code>	A vector of length m of p-values for test of treatment effect for individual comparisons (common / random effects model).
<code>leverage.common</code>	A vector of length m of leverages, interpretable as factors by which variances are reduced using information from the whole network.
<code>w.common</code> , <code>w.random</code>	A vector of length m of weights of individual studies (common / random effects model).
<code>Q.common</code>	A vector of length m of contributions to total heterogeneity / inconsistency statistic.

TE.common, TE.random
nxn matrix with estimated overall treatment effects (common / random effects model).

seTE.common, seTE.random
nxn matrix with standard errors (common / random effects model).

lower.common, upper.common, lower.random, upper.random
nxn matrices with lower and upper confidence interval limits (common / random effects model).

statistic.common, pval.common, statistic.random, pval.random
nxn matrices with z-value and p-value for test of overall treatment effect (common / random effects model).

seTE.predict *nxn* matrix with standard errors for prediction intervals.

lower.predict, upper.predict
nxn matrices with lower and upper prediction interval limits.

prop.direct.common, prop.direct.random
A named vector of the direct evidence proportion of each network estimate. (common effects / random effects model).

TE.direct.common, TE.direct.random
nxn matrix with estimated treatment effects from direct evidence (common effects / random effects model).

seTE.direct.common, seTE.direct.random
nxn matrix with estimated standard errors from direct evidence (common effects / random effects model).

lower.direct.common, upper.direct.common, lower.direct.random, upper.direct.random
nxn matrices with lower and upper confidence interval limits from direct evidence (common / random effects model).

statistic.direct.common, pval.direct.common, statistic.direct.random, pval.direct.random
nxn matrices with z-value and p-value for test of overall treatment effect from direct evidence (common / random effects model).

TE.indirect.common, TE.indirect.random
nxn matrix with estimated treatment effects from indirect evidence (common / random effects model).

seTE.indirect.common, seTE.indirect.random
nxn matrix with estimated standard errors from indirect evidence (common / random effects model).

lower.indirect.common, upper.indirect.common, lower.indirect.random, upper.indirect.random
nxn matrices with lower and upper confidence interval limits from indirect evidence (common / random effects model).

statistic.indirect.common, pval.indirect.common, statistic.indirect.random, pval.indirect.random
nxn matrices with z-value and p-value for test of overall treatment effect from indirect evidence (common / random effects model).

Q Overall heterogeneity / inconsistency statistic.

df.Q	Degrees of freedom for test of heterogeneity / inconsistency.
pval.Q	P-value for test of heterogeneity / inconsistency.
I2, lower.I2, upper.I2	I-squared, lower and upper confidence limits.
tau	Square-root of between-study variance.
Q.heterogeneity	Overall heterogeneity statistic.
df.Q.heterogeneity	Degrees of freedom for test of overall heterogeneity.
pval.Q.heterogeneity	P-value for test of overall heterogeneity.
Q.inconsistency	Overall inconsistency statistic.
df.Q.inconsistency	Degrees of freedom for test of overall inconsistency.
pval.Q.inconsistency	P-value for test of overall inconsistency.
Q.decomp	Data frame with columns 'treat1', 'treat2', 'Q', 'df' and 'pval.Q', providing heterogeneity statistics for each pairwise meta-analysis of direct comparisons.
A.matrix	Adjacency matrix (nxn).
X.matrix	Design matrix (mxn).
B.matrix	Edge-vertex incidence matrix (mxn).
L.matrix.common, L.matrix.random	Laplacian matrix (nxn).
Lplus.matrix.common, Lplus.matrix.random	Moore-Penrose pseudoinverse of the Laplacian matrix (nxn).
Q.matrix	Matrix of heterogeneity statistics for pairwise meta-analyses, where direct comparisons exist (nxn).
G.matrix	Matrix with variances and covariances of comparisons (mxm). G is defined as $\mathbf{BL+B^t}$.
H.matrix.common, H.matrix.random	Hat matrix (mxm), defined as $\mathbf{H = GW = BL+B^tW}$.
n.matrix	nxn matrix with number of observations in direct comparisons (if arguments n1 and n2 are provided).
events.matrix	nxn matrix with number of events in direct comparisons (if arguments event1 and event2 are provided).
P.common, P.random	nxn matrix with direct evidence proportions (common / random effects model).
Cov.common	Variance-covariance matrix (common effects model)
Cov.random	Variance-covariance matrix (random effects model)
sm, level, level.ma	As defined above.

common, random As defined above.
 prediction, level.predict
 As defined above.
 reference.group, baseline.reference, small.values, all.treatments
 As defined above.
 seq, tau.preset, tol.multiarm, tol.multiarm.se
 As defined above.
 details.chkmultiarm, sep.trts, nchar.trts
 As defined above.
 backtransf, title, warn, warn.deprecated
 As defined above.
 call Function call.
 version Version of R package netmeta used to create object.

In addition, the following component is stored if **metafor** is used to calculate the between-study variance and argument `keepprma = TRUE`:

`rma.tau` R object created with `rma.mv`.

Note

R function `rma.mv` from R package **metafor** (Viechtbauer 2010) is called internally to estimate the between-study variance τ^2 for the (restricted) maximum likelihood method. For binary outcomes, incidence rates, and the mean difference, the variance-covariance matrix is calculated if arguments `event1`, `event2`, `n1`, and `n2` (binary outcomes); `event1`, `event2`, `time1`, and `time2` (incidence rates); `n1`, `n2`, `sd1`, and `sd2` (mean difference) are provided. For datasets preprocessed with `pairwise` the respective variables are selected automatically.

netmetabin

Network meta-analysis of binary outcome data

Description

Provides four models for the network meta-analysis of binary data (Mantel-Haenszel method, based on the non-central hypergeometric distribution, penalised logistic regression, and the inverse variance method).

Usage

```
netmetabin(
  event1,
  n1,
  event2,
  n2,
  treat1,
  treat2,
  studlab,
  data = NULL,
  subset = NULL,
  sm,
  method = "MH",
  cc.pooled = FALSE,
  incr,
  method.incr,
  allstudies,
  level = gs("level"),
  level.ma = gs("level.ma"),
  common = gs("common"),
  random = method %in% c("Inverse", "LRP") & (gs("random") | !is.null(tau.preset)),

  seq = gs("seq"),
  tau.preset = NULL,
  tol.multiarm = 0.001,
  tol.multiarm.se = NULL,
  details.chkmultiarm = FALSE,
  details.chkdata = TRUE,
```

```

sep.trts = ":",
nchar.trts = 666,
func.inverse = invmat,
overall.hetstat = gs("overall.hetstat"),
backtransf = gs("backtransf"),
title = gs("title"),
keepdata = gs("keepdata"),
addincr,
allincr,
warn = gs("warn"),
warn.deprecated = gs("warn.deprecated"),
...
)

```

Arguments

event1	Number of events (first treatment).
n1	Number of observations (first treatment).
event2	Number of events (second treatment).
n2	Number of observations (second treatment)
treat1	Label/Number for first treatment.
treat2	Label/Number for second treatment.
studlab	An optional - but important! - vector with study labels (see Details).
data	An optional data frame containing the study information.
subset	An optional vector specifying a subset of studies to be used.
sm	A character string indicating underlying summary measure, i.e., "RD", "RR", "OR", "ASD".
method	A character string indicating which method is to be used for pooling of studies. One of "MH", "NCH", "LRP", or "Inverse", can be abbreviated.
cc.pooled	A logical indicating whether incr should be used as a continuity correction, when calculating the network meta-analysis estimates (ignored for penalised logistic regression and inverse variance method).
incr	A numerical value which is added to each cell count, i.e., to the numbers of events and non-events, of all treatment arms in studies with zero events or non-events in any of the treatment arms ("continuity correction").
method.incr	A character string indicating which continuity correction method should be used ("only0", "if0all", or "all"), see metabin .
allstudies	A logical indicating whether studies with zero events or non-events in all treatment arms should be included in an inverse variance meta-analysis (applies only if method = "Inverse" and sm is equal to either "RR" or "OR").
level	The level used to calculate confidence intervals for individual studies.
level.ma	The level used to calculate confidence intervals for network estimates.
common	A logical indicating whether a common effects network meta-analysis should be conducted.

random	A logical indicating whether a random effects network meta-analysis should be conducted.
prediction	A logical indicating whether a prediction interval should be printed (only considered if method = "Inverse").
level.predict	The level used to calculate prediction interval for a new study (only considered if method = "Inverse").
reference.group	Reference treatment.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if reference.group has been specified.
small.values	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect (passed on to netrank , can be abbreviated).
all.treatments	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
seq	A character or numerical vector specifying the sequence of treatments in printouts.
tau.preset	An optional value for manually setting the square-root of the between-study variance τ^2 (only considered if method = "Inverse").
tol.multiarm	A numeric for the tolerance for consistency of treatment estimates in multi-arm studies which are consistent by design (only considered if method = "Inverse").
tol.multiarm.se	A numeric for the tolerance for consistency of standard errors in multi-arm studies which are consistent by design (only considered if the argument is not NULL and method = "Inverse").
details.chkmultiarm	A logical indicating whether treatment estimates and / or variances of multi-arm studies with inconsistent results or negative multi-arm variances should be printed (only considered if method = "Inverse").
details.chkdata	A logical indicating whether number of events and participants of studies with inconsistent data should be printed.
sep.trts	A character used in comparison names as separator between treatment labels.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names (see Details).
func.inverse	R function used to calculate the pseudoinverse of the Laplacian matrix L (see netmeta).
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.

title	Title of meta-analysis / systematic review.
keepdata	A logical indicating whether original data(set) should be kept in netmeta object.
addincr	Deprecated argument (replaced by 'method.incr'); see metabin .
allincr	Deprecated argument (replaced by 'method.incr'); see metabin .
warn	A logical indicating whether warnings should be printed (e.g., if studies are excluded from meta-analysis due to zero standard errors).
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).

Details

This function implements four models for the network meta-analysis of binary data:

- The Mantel-Haenszel network meta-analysis model, as described in Efthimiou et al. (2019) (`method = "MH"`);
- a network meta-analysis model using the non-central hypergeometric distribution with the Breslow approximation, as described in Stijnen et al. (2010) (`method = "NCH"`);
- a logistic regression with penalised likelihood, as described in Evrenoglou et al. (2022) (`method = "LRP"`);
- the inverse variance method for network meta-analysis (`method = "Inverse"`), also provided by [netmeta](#).

Comparisons belonging to multi-arm studies are identified by identical study labels (argument `studlab`). It is therefore important to use identical study labels for all comparisons belonging to the same multi-arm study.

Data entry for this function is in *contrast-based* format, that is, each line of the data corresponds to a single pairwise comparison between two treatments (arguments `treat1`, `treat2`, `event1`, `n1`, `event2`, and `n2`). If data are provided in *arm-based* format, that is, number of events and participants are given for each treatment arm separately, function [pairwise](#) can be used to transform the data to *contrast-based* format (see help page of function [pairwise](#)).

Note, all pairwise comparisons must be provided for a multi-arm study. Consider a multi-arm study of p treatments with known variances. For this study, the number of events and observations must be provided for each treatment, for each of $p(p - 1) / 2$ possible comparisons in separate lines in the data. For instance, a three-arm study contributes three pairwise comparisons, a four-arm study even six pairwise comparisons. Function [pairwise](#) automatically calculates all pairwise comparisons for multi-arm studies.

For `method = "Inverse"`, both common and random effects models are calculated regardless of values chosen for arguments `common` and `random`. Accordingly, the network estimates for the random effects model can be extracted from component `TE.random` of an object of class "netmeta" even if argument `random = FALSE`. However, all functions in R package **netmeta** will adequately consider the values for `common` and `random`. E.g. function [print.summary.netmeta](#) will not print results for the random effects model if `random = FALSE`.

For the random-effects model, the direct treatment estimates are based on the common between-study variance τ^2 from the network meta-analysis.

For `method = "MH"` and `method = "NCH"`, only a common effects model is available.

By default, treatment names are not abbreviated in printouts. However, in order to get more concise printouts, argument `nchar.trts` can be used to define the minimum number of characters for abbreviated treatment names (see [abbreviate](#), argument `minlength`). R function `treats` is utilised internally to create abbreviated treatment names.

Names of treatment comparisons are created by concatenating treatment labels of pairwise comparisons using `sep.trts` as separator (see [paste](#)). These comparison names are used in the covariance matrices `Cov.common` and `Cov.random` and in some R functions, e.g. `decomp.design`. By default, a colon is used as the separator. If any treatment label contains a colon the following characters are used as separator (in consecutive order): "-", "_", "/", "+", ".", "|", and "*". If all of these characters are used in treatment labels, a corresponding error message is printed asking the user to specify a different separator.

Value

An object of class `netmetabin` and `netmeta` with corresponding `print`, `summary`, `forest`, and `netrank` functions. The object is a list containing the following components:

<code>studlab</code> , <code>treat1</code> , <code>treat2</code>	As defined above.
<code>n1</code> , <code>n2</code> , <code>event1</code> , <code>event2</code>	As defined above.
<code>TE</code>	Estimate of treatment effect, i.e. difference between first and second treatment (e.g. log odds ratio).
<code>seTE</code>	Standard error of treatment estimate.
<code>k</code>	Total number of studies.
<code>m</code>	Total number of pairwise comparisons.
<code>n</code>	Total number of treatments.
<code>d</code>	Total number of designs (corresponding to the unique set of treatments compared within studies).
<code>trts</code>	Treatments included in network meta-analysis.
<code>k.trts</code>	Number of studies evaluating a treatment.
<code>n.trts</code>	Number of observations receiving a treatment.
<code>events.trts</code>	Number of events observed for a treatment.
<code>studies</code>	Study labels coerced into a factor with its levels sorted alphabetically.
<code>narms</code>	Number of arms for each study.
<code>designs</code>	Unique list of designs present in the network. A design corresponds to the set of treatments compared within a study.
<code>TE.common</code> , <code>seTE.common</code>	$n \times n$ matrix with estimated overall treatment effects and standard errors for common effects model.
<code>lower.common</code> , <code>upper.common</code>	$n \times n$ matrices with lower and upper confidence interval limits for common effects model.

statistic.common, pval.common	<i>nxn</i> matrices with z-value and p-value for test of overall treatment effect under common effects model.
TE.random, seTE.random	<i>nxn</i> matrix with estimated overall treatment effects and standard errors for random effects model (only available if method = "Inverse").
lower.random, upper.random	<i>nxn</i> matrices with lower and upper confidence interval limits for random effects model (only available if method = "Inverse").
statistic.random, pval.random	<i>nxn</i> matrices with z-value and p-value for test of overall treatment effect under random effects model (only available if method = "Inverse").
TE.direct.common, seTE.direct.common	<i>nxn</i> matrix with estimated treatment effects and standard errors from direct evidence under common effects model.
lower.direct.common, upper.direct.common	<i>nxn</i> matrices with lower and upper confidence interval limits from direct evidence under common effects model.
statistic.direct.common, pval.direct.common	<i>nxn</i> matrices with z-value and p-value for test of overall treatment effect from direct evidence under common effects model.
TE.direct.random, seTE.direct.random	<i>nxn</i> matrix with estimated treatment effects and standard errors from direct evidence under random effects model (only available if method = "Inverse").
lower.direct.random, upper.direct.random	<i>nxn</i> matrices with lower and upper confidence interval limits from direct evidence under random effects model (only available if method = "Inverse").
statistic.direct.random, pval.direct.random	<i>nxn</i> matrices with z-value and p-value for test of overall treatment effect from direct evidence under random effects model (only available if method = "Inverse").
Q	Overall heterogeneity / inconsistency statistic. (only available if method = "Inverse")
df.Q	Degrees of freedom for test of heterogeneity / inconsistency.
pval.Q	P-value for test of heterogeneity / inconsistency.
I2, lower.I2, upper.I2	I-squared, lower and upper confidence limits (only available if method = "Inverse").
tau	Square-root of between-study variance (only available if method = "Inverse").
Q.heterogeneity	Overall heterogeneity statistic. (only available if method = "Inverse")
df.Q.heterogeneity	Degrees of freedom for test of overall heterogeneity.
pval.Q.heterogeneity	P-value for test of overall heterogeneity.
Q.inconsistency	Overall inconsistency statistic.
df.Q.inconsistency	Degrees of freedom for test of overall inconsistency.

pval.Q.inconsistency	P-value for test of overall inconsistency.
A.matrix	Adjacency matrix (nxn).
H.matrix.common	Hat matrix (mxm)
n.matrix	nxn matrix with number of observations in direct comparisons.
events.matrix	nxn matrix with number of events in direct comparisons.
sm, method, level, level.ma	As defined above.
incr, method.incr, allstudies, cc.pooled	As defined above.
addincr, allincr	As defined above.
common, random	As defined above.
prediction, level.predict	As defined above.
reference.group, baseline.reference, small.values, all.treatments	As defined above.
seq, tau.preset, tol.multiarm, tol.multiarm.se	As defined above.
details.chkmultiarm, details.chkdata	As defined above.
sep.trts, nchar.trts, overall.hetstat	As defined above.
backtransf, title, warn, warn.deprecated	As defined above.
data	Dataset (in contrast-based format).
data.design	List with data in arm-based format (each list element corresponds to a single design).
call	Function call.
version	Version of R package netmeta used to create object.

netmetareg.netmeta *Network meta-regression with a single continuous or binary covariate*

Description

Network meta-regression with a single continuous or binary covariate for objects of class `netmeta`. This is a wrapper function for the R function `rma.mv` in the R package **metafor** (Viechtbauer 2010).

Usage

```
## S3 method for class 'netmeta'
netmetareg(
  x,
  covar = NULL,
  consistency = TRUE,
  assumption = "independent",
  method.tau = if (!x$random) "FE" else "REML",
```

```

    level = x$level.ma,
    reference.group = x$reference.group,
    nchar.trts = x$nchar.trts,
    ...
)

netmetareg(x, ...)

## Default S3 method:
netmetareg(x, ...)

## S3 method for class 'netmetareg'
print(
  x,
  digits = gs("digits"),
  digits.se = gs("digits.se"),
  digits.stat = gs("digits.stat"),
  digits.pval = gs("digits.pval"),
  print.se = FALSE,
  details.methods = TRUE,
  ...
)

```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>covar</code>	Continuous or binary covariate.
<code>consistency</code>	A logical indicating whether a consistency or inconsistency model should be assumed.
<code>assumption</code>	A character string indicating which assumption is done for the covariate; either "independent" or "common" (can be abbreviated).
<code>method.tau</code>	A character string indicating which method is used to estimate the between-study variance tau-squared. Either "FE", "REML", or "ML".
<code>level</code>	The level used to calculate confidence intervals for regression coefficients.
<code>reference.group</code>	Reference treatment.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>...</code>	Additional arguments passed to R function <code>rma.uni</code> .
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .
<code>digits.se</code>	Minimal number of significant digits for standard errors.
<code>digits.stat</code>	Minimal number of significant digits for z- or t-value, see <code>print.default</code> .
<code>digits.pval</code>	Minimal number of significant digits for p-value of overall treatment effect, see <code>print.default</code> .
<code>print.se</code>	A logical specifying whether standard errors should be printed.

details.methods

A logical specifying whether details on statistical methods should be printed.

Details

This R function is a wrapper function for R function [rma.mv](#) in the R package **metafor** (Viechtbauer 2010).

Note, results are not back-transformed in printouts of network meta-analyses using summary measures with transformations, e.g., log risk ratios are printed instead of the risk ratio if argument `sm = "RR"`.

Argument `'...'` can be used to pass additional arguments to R function [rma.mv](#). For example, argument `control` to provide a list of control values for the iterative estimation algorithm. See help page of R function [rma.mv](#) for more details.

Value

An object of class `c("netmetareg", "rma.mv", "rma")`. Please look at the help page of R function [rma.mv](#) for more details on the output from this function.

In addition, a list `.netmeta` is added to the output containing the following components:

`x`, `covar`, `method.tau`

As defined above.

`dots`

Information provided in argument `'...'`.

`call`

Function call.

`version`

Version of R package **netmeta** used to create object.

`version.metafor`

Version of R package **metafor** used to create object.

Arguments

x	An object of class netmeta or netpairwise.
...	Additional arguments (passed on to metagen or print functions and to catch deprecated arguments).
separate	A logical indicating whether results for pairwise comparisons should be printed as separate meta-analyses or as subgroups which is more concise.
common	A logical indicating whether a common effects network meta-analysis should be conducted.
random	A logical indicating whether a random effects network meta-analysis should be conducted.
level	The level used to calculate confidence intervals for individual comparisons.
level.ma	The level used to calculate confidence intervals for pooled estimates.
prediction	A logical indicating whether prediction intervals should be printed.
level.predict	The level used to calculate prediction intervals for a new study.
reference.group	Reference treatment.

baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if <code>reference.group</code> has been specified.
method.tau	A character string indicating which method is used to estimate the between-study variance τ^2 and its square root τ . Either "DL", "REML", or "ML", can be abbreviated.
order	An optional character or numerical vector specifying the order of treatments.
sep.trts	A character used in comparison names as separator between treatment labels.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names (see Details).
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
method	A character string indicating which method is to be used for pooling of studies, see metabin .
incr	A numerical value which is added to cell counts, see metabin .
method.incr	A character string indicating which continuity correction method should be used ("only0", "if0all", or "all"), see metabin .
allstudies	A logical indicating whether studies with zero events or non-events in all treatment arms should be included in the meta-analysis, see metabin .
object	An object of class <code>netpairwise</code> .
k.min	Minimum number of studies in pairwise comparison to show funnel plot, radial plot or conduct test for funnel plot asymmetry.

Details

Conduct pairwise meta-analyses for all comparisons with direct evidence in a network meta-analysis. In contrast to [netmeta](#) and [netsplit](#), unadjusted standard errors are used in the calculations and the between-study heterogeneity variance is allowed to differ between comparisons.

The R function [metagen](#) is called internally.

Value

Either a single [metagen](#) object with pairwise comparisons as subgroups or a list with [metagen](#) objects for each direct pairwise comparison.

Note

This function must not be confused with [pairwise](#) which can be used as a pre-processing step to convert data from arm-based to contrast-based format by calculating all pairwise comparisons within a study.

netposet

Partial order of treatments in network meta-analysis

Description

Partial order of treatments in network meta-analysis. The set of treatments in a network is called a partially ordered set (in short, a *poset*), if different outcomes provide different treatment ranking lists.

Usage

```
netposet(
  ...,
  outcomes,
  treatments,
  small.values,
  common,
  random,
  fixed,
  comb.fixed,
  comb.random
)

## S3 method for class 'netposet'
print(x, pooled = ifelse(x$random, "random", "common"), ...)
```

Arguments

...	See details.
outcomes	A character vector with outcome names.
treatments	A character vector with treatment names.
small.values	See details.
common	A logical indicating whether to show results for the common effects model.
random	A logical indicating whether to show results for the random effects model.
fixed	Ignored deprecated argument (replaced by common).
comb.fixed	Ignored deprecated argument (replaced by common).
comb.random	Ignored deprecated argument (replaced by random).
x	An object of class netposet.
pooled	A character string indicating whether Hasse diagram should be drawn for common ("common") or random effects model ("random"). Can be abbreviated.

Details

In network meta-analysis, frequently different outcomes are considered which may each provide a different ordering of treatments. The concept of a partially ordered set (in short, a *poset*, Carlsen & Bruggemann, 2014) of treatments can be used to gain further insights in situations with apparently conflicting orderings. This implementation for rankings in network meta-analysis is described in Rucker & Schwarzer (2017).

In function `netposet`, argument `...{}` can be any of the following:

- arbitrary number of `netrank` objects providing P-scores;
- arbitrary number of `netmeta` objects;
- single ranking matrix with each column providing P-scores (Rucker & Schwarzer 2015) or SUCRA values (Salanti et al. 2011) for an outcome and rows corresponding to treatments.

Note, albeit in general a ranking matrix is not constrained to have values between 0 and 1, `netposet` stops with an error in this case as this function expects a matrix with P-scores or SUCRA values.

Argument `outcomes` can be used to label outcomes. If argument `outcomes` is missing,

- column names of the ranking matrix are used as outcome labels (if first argument is a ranking matrix and column names are available);
- capital letters 'A', 'B', ... are used as outcome labels and a corresponding warning is printed.

Argument `treatments` can be used to provide treatment labels if the first argument is a ranking matrix. If argument `treatment` is missing,

- row names of the ranking matrix are used as treatment labels (if available);
- letters 'a', 'b', ... are used as treatment labels and a corresponding warning is printed.

If argument `...{}` consists of `netmeta` objects, `netrank` is called internally to calculate P-scores. In this case, argument `small.values` can be used to specify for each outcome whether small values are beneficial ("desirable") or harmful ("undesirable"); see `netrank`. This argument is ignored for a ranking matrix and `netrank` objects.

Arguments `common` and `random` can be used to define whether results should be printed and plotted for common and random effects model. If `netmeta` and `netrank` objects are provided in argument `...{}`, values for `common` and `random` within these objects are considered; if these values are not unique, argument `common` or `random` are set to TRUE.

In function `print.netposet`, argument `...{}` is passed on to the printing function.

Value

An object of class `netposet` with corresponding `print`, `plot`, and `hasse` functions. The object is a list containing the following components:

<code>P.common</code>	Ranking matrix with rows corresponding to treatments and columns corresponding to outcomes (common effects model).
<code>M0.common</code>	Hasse matrix skipping unnecessary paths (common effects model).
<code>M.common</code>	"Full" Hasse matrix (common effects model).
<code>O.common</code>	Matrix with information about partial ordering (common effects model).

P.random	Ranking matrix with rows corresponding to treatments and columns corresponding to outcomes (random effects model).
M0.random	Hasse matrix skipping unnecessary paths (random effects model).
M.random	"Full" Hasse matrix (random effects model).
O.random	Matrix with information about partial ordering (random effects model).
small.values, common, random	As.defined above.
call	Function call.
version	Version of R package netmeta used to create object.

netrank

Frequentist method to rank treatments in network

Description

Ranking treatments in frequentist network meta-analysis with and without resampling methods.

Usage

```

netrank(
  x,
  small.values = x$small.values,
  method,
  nsim,
  common = x$common,
  random = x$random,
  warn.deprecated = gs("warn.deprecated"),

```

```

    ...
  )

## S3 method for class 'netrank'
print(
  x,
  common = x$common,
  random = x$random,
  sort = TRUE,
  digits = gs("digits.prop"),
  warn.deprecated = gs("warn.deprecated"),
  ...
)

```

Arguments

<code>x</code>	An object of class <code>netmeta</code> or <code>rankogram</code> .
<code>small.values</code>	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect, can be abbreviated.
<code>method</code>	A character string specifying whether the "P-score" or "SUCRA" ranking metric will be calculated.
<code>nsim</code>	Number of simulations to calculate SUCRAs.
<code>common</code>	A logical indicating whether to print P-scores or SUCRAs for the common effects model.
<code>random</code>	A logical indicating whether to print P-scores or SUCRAs for the random effects model.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments passed on to <code>print.data.frame</code> function (used internally).
<code>sort</code>	A logical indicating whether printout should be sorted by decreasing P-score.
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .

Details

Treatments are ranked based on a network meta-analysis. Ranking is performed by a ranking metric: P-score or SUCRA.

P-scores are based solely on the point estimates and standard errors of the network estimates. They measure the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Rücker and Schwarzer 2015).

The Surface Under the Cumulative RAnking curve (SUCRA) is the rank of treatment i within the range of treatments, measured on a scale from 0 (worst) to 1 (best) (Salanti et al. 2011). A resampling method is used to calculate SUCRAs for frequentist network meta-analysis. The number of simulations is determine by argument `nsim`.

The interpretation of P-scores and SUCRAs is comparable.

The P-score of treatment i is defined as the mean of all $1 - P[j]$ where $P[j]$ denotes the one-sided P-value of accepting the alternative hypothesis that treatment i is better than one of the competing treatments j . Thus, if treatment i is better than many other treatments, many of these P-values will be small and the P-score will be large. Vice versa, if treatment i is worse than most other treatments, the P-score is small.

The P-score of treatment i can be interpreted as the mean extent of certainty that treatment i is better than another treatment.

Value

An object of class `netrank` with corresponding `print` function. The object is a list containing the following components:

<code>ranking.common</code>	A named numeric vector with P-scores or SUCRAs for the common effects model.
<code>Pmatrix.common</code>	Numeric matrix based on pairwise one-sided p-values for the common effects model.
<code>ranking.random</code>	A named numeric vector with P-scores or SUCRAs for the random effects model.
<code>Pmatrix.random</code>	Numeric matrix based on pairwise one-sided p-values of the random effects model.
<code>small.values, method, x</code>	As defined above.
<code>version</code>	Version of R package <code>netmeta</code> used to create object.

 netsplit

Split direct and indirect evidence in network meta-analysis

Description

Methods to split network estimates into the contribution of direct and indirect evidence and to test for local inconsistency in network meta-analysis.

Usage

```

netsplit(
  x,
  method,
  upper = TRUE,
  reference.group = x$reference.group,
  baseline.reference = x$baseline.reference,
  show = gs("show"),
  overall = TRUE,
  direct = TRUE,
  indirect = TRUE,
  only.reference = FALSE,
  ci = FALSE,
  test = show %in% c("all", "with.direct", "both"),
  order = NULL,
  sep.trts = x$sep.trts,
  quote.trts = "",
  tol.direct = 5e-04,
  common = x$common,
  random = x$random,
  backtransf = x$backtransf,
  warn = FALSE,

```

```

warn.deprecated = gs("warn.deprecated"),
verbose = FALSE,
...
)

## S3 method for class 'netsplit'
print(

  nchar.trts = x$nchar.trts,
  digits = gs("digits"),
  digits.stat = gs("digits.stat"),
  digits.pval = gs("digits.pval"),
  digits.prop = max(gs("digits.pval") - 2, 2),
  text.NA = gs("lab.NA"),
  backtransf = x$backtransf,
  scientific.pval = gs("scientific.pval"),
  big.mark = gs("big.mark"),
  legend = gs("legend"),
  indent = TRUE,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

```

Arguments

<code>x</code>	An object of class <code>netmeta</code> or <code>netsplit</code> .
<code>method</code>	A character string indicating which method to split direct and indirect evidence is to be used. Either "Back-calculation" or "SIDDE", can be abbreviated. See Details.
<code>upper</code>	A logical indicating whether treatment comparisons should be selected from the lower or upper triangle of the treatment effect matrices (see list elements <code>TE.common</code> and <code>TE.random</code> in the <code>netmeta</code> object). Ignored if argument order is provided.
<code>reference.group</code>	Reference treatment. Ignored if argument order is provided.
<code>baseline.reference</code>	A logical indicating whether results should be expressed as comparisons of other

	treatments versus the reference treatment or vice versa. This argument is only considered if <code>reference.group</code> is not equal to "" and <code>argumentorder</code> is not provided.
<code>show</code>	A character string indicating which comparisons should be printed (see Details).
<code>overall</code>	A logical indicating whether estimates from network meta-analysis should be printed.
<code>direct</code>	A logical indicating whether direct estimates should be printed.
<code>indirect</code>	A logical indicating whether indirect estimates should be printed.
<code>only.reference</code>	A logical indicating whether only comparisons with the reference group should be printed.
<code>ci</code>	A logical indicating whether confidence intervals should be printed in addition to treatment estimates.
<code>test</code>	A logical indicating whether results of a test comparing direct and indirect estimates should be printed.
<code>order</code>	A optional character or numerical vector specifying the order of treatments in comparisons.
<code>sep.trts</code>	A character string used in comparison names as separator between treatment labels, e.g., " vs ".
<code>quote.trts</code>	A character used to print around treatment labels.
<code>tol.direct</code>	A numeric defining the maximum deviation of the direct evidence proportion from 0 or 1 to classify a comparison as providing only indirect or direct evidence, respectively.
<code>common</code>	A logical indicating whether results for the common effects network meta-analysis should be printed.
<code>random</code>	A logical indicating whether results for the random effects network meta-analysis should be printed.
<code>backtransf</code>	A logical indicating whether printed results should be back transformed. For example, if <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are printed as odds ratios rather than log odds ratios.
<code>warn</code>	A logical indicating whether warnings should be printed.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>verbose</code>	A logical indicating whether progress information should be printed.
<code>...</code>	Additional arguments.
<code>sortvar</code>	An optional vector used to sort comparisons (must be of same length as the total number of comparisons).
<code>subset</code>	An optional logical vector specifying a subset of comparisons to print (must be of same length as the total number of comparisons) .
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .

<code>digits.stat</code>	Minimal number of significant digits for z-value of test of agreement between direct and indirect evidence, see <code>print.default</code> .
<code>digits.pval</code>	Minimal number of significant digits for p-value of test of agreement between direct and indirect evidence, see <code>print.default</code> .
<code>digits.prop</code>	Minimal number of significant digits for direct evidence proportions, see <code>print.default</code> .
<code>text.NA</code>	A character string specifying text printed for missing values.
<code>scientific.pval</code>	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
<code>big.mark</code>	A character used as thousands separator.
<code>legend</code>	A logical indicating whether a legend should be printed.
<code>indent</code>	A logical indicating whether items in the legend should be indented.

Details

A comparison of direct and indirect treatment estimates can serve as check for consistency of network meta-analysis (Dias et al., 2010).

This function provides two methods to derive indirect estimates:

- Separate Indirect from Direct Evidence (SIDE) using a back-calculation method (`method = "Back-calculation"`) based on the *direct evidence proportion* to calculate the indirect evidence (König et al., 2013);
- Separate Indirect from Direct Design Evidence (SIDDE) as described in Efthimiou et al. (2019).

Note, for the back-calculation method, indirect treatment estimates are already calculated in [netmeta](#) and this function combines and prints these estimates in a user-friendly way. Furthermore, this method is not available for the Mantel-Haenszel and non-central hypergeometric distribution approach implemented in [netmetabin](#).

For the random-effects model, the direct treatment estimates are based on the common between-study variance τ^2 from the network meta-analysis, i.e. the square of list element `x$tau`.

Argument `show` determines which comparisons are printed:

<code>"all"</code>	All comparisons
<code>"both"</code>	Only comparisons contributing both direct and indirect evidence
<code>"with.direct"</code>	Comparisons providing direct evidence
<code>"direct.only"</code>	Comparisons providing only direct evidence
<code>"indirect.only"</code>	Comparisons providing only indirect evidence

The node-splitting method and SIDDE can be compute-intensive in large networks. Crude information on the computation progress is printed if argument `verbose = TRUE`. In addition, computation times are printed if R package **tictoc** is installed.

Value

An object of class `netsplit` with corresponding `print` and `forest` functions. The object is a list containing the following components:

<code>common</code> , <code>random</code>	As defined above.
<code>comparison</code>	A vector with treatment comparisons.
<code>prop.common</code> , <code>prop.random</code>	A vector with direct evidence proportions (common / random effects model).
<code>common</code> , <code>random</code>	Results of network meta-analysis (common / random effects model), i.e., data frame with columns <code>comparison</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , and <code>p</code> .
<code>direct.common</code> , <code>direct.random</code>	Network meta-analysis results based on direct evidence (common / random effects model), i.e., data frame with columns <code>comparison</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , and <code>p</code> .
<code>indirect.common</code> , <code>indirect.random</code>	Network meta-analysis results based on indirect evidence (common / random effects model), i.e., data frame with columns <code>comparison</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , and <code>p</code> .
<code>compare.common</code> , <code>compare.random</code>	Comparison of direct and indirect evidence in network meta-analysis (common / random effects model), i.e., data frame with columns <code>comparison</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , and <code>p</code> .
<code>sm</code>	A character string indicating underlying summary measure
<code>level.ma</code>	The level used to calculate confidence intervals for pooled estimates.
<code>tictoc</code>	Computation times for node-splitting method or SIDDE (if R package tictoc is installed).
<code>version</code>	Version of R package <code>netmeta</code> used to create object.

)

## S3 method for class 'nettable'
print(x, common = x$x$common, random = x$x$random, legend = gs("legend"), ...)

```

Arguments

...	Any number of network meta-analysis objects or a single list with network meta-analyses.
name	An optional character vector providing descriptive names for network meta-analysis objects.
method	A character string indicating which method to split direct and indirect evidence is to be used. Either "Back-calculation" or "SIDDE", can be abbreviated. See Details.
order	A optional character or numerical vector specifying the order of treatments in comparisons.
common	A logical indicating whether table for the common effects network meta-analysis should be printed.
random	A logical indicating whether table for the random effects network meta-analysis should be printed.
upper	A logical indicating whether treatment comparisons should be selected from the lower or upper triangle of the treatment effect matrices (see list elements TE.common and TE.random in the netmeta object). Ignored if argument order is provided.
reference.group	Reference treatment. Ignored if argument order is provided.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment or vice versa. This argument is only considered if reference.group is not equal to "" and argumentorder is not provided.

backtransf	A logical indicating whether printed results should be back transformed. For example, if backtransf = TRUE, results for sm = "OR" are printed as odds ratios rather than log odds ratios.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
digits	Minimal number of significant digits, see print.default.
digits.I2	Minimal number of significant digits for I-squared statistic, see print.default.
digits.pval	Minimal number of significant digits for p-value of test of agreement between direct and indirect evidence, see print.default.
scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval	A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval	A logical specifying whether p-values for test of overall effect should be printed according to JAMA reporting standards.
big.mark	A character used as thousands separator.
text.NA	A character string specifying text printed for missing values.
bracket	A character with bracket symbol to print lower confidence interval: "[", "(", "{", "".
separator	A character string with information on separator between lower and upper confidence interval.
lower.blank	A logical indicating whether blanks between left bracket and lower confidence limit should be printed.
upper.blank	A logical indicating whether blanks between separator and upper confidence limit should be printed.
tol.direct	A numeric defining the maximum deviation of the direct evidence proportion from 0 or 1 to classify a comparison as providing only indirect or direct evidence, respectively.
writexl	A logical indicating whether an Excel file should be created (R package writexl must be available).
path	A character string specifying the filename of the Excel file.
overwrite	A logical indicating whether an existing Excel file should be overwritten.
warn	A logical indicating whether warnings should be printed.
verbose	A logical indicating whether progress information should be printed.
x	An object of class nettable.
legend	A logical indicating whether a legend should be printed for abbreviated treatment names.

Details

Construct a table with network, direct and indirect estimates from one or more network meta-analyses. The table looks very similar to the statistical part of a GRADE table for a network meta-analysis (Puhan et al., 2014).

By default, an R object with the network tables is generated. Alternatively, an Excel file is created if argument `writexl = TRUE`.

Two methods to derive indirect estimates are available:

- Separate Indirect from Direct Evidence (SIDE) using a back-calculation method (`method = "Back-calculation"`) based on the *direct evidence proportion* to calculate the indirect evidence (König et al., 2013);
- Separate Indirect from Direct Design Evidence (SIDDE) as described in Efthimiou et al. (2019).

Note, for the back-calculation method, indirect treatment estimates are already calculated in `netmeta` and this function combines and prints these estimates in a user-friendly way. Furthermore, this method is not available for the Mantel-Haenszel and non-central hypergeometric distribution approach implemented in `netmetabin`.

For the random-effects model, the direct treatment estimates are based on the common between-study variance τ^2 from the network meta-analysis, i.e. the square of list element `x$tau`.

The SIDDE approach can be compute-intensive in large networks. Crude information on the computation progress is printed for SIDDE if argument `verbose` is `TRUE`.

Value

An object of class `nettable` with corresponding `print` function if argument `writexl = FALSE`. The object is a list containing the network tables in list elements `'common'` and `'random'`. An Excel file is created if `writexl = TRUE`. In this case, `NULL` is returned in R.

plot.netposet

Scatter plot or biplot showing partially order of treatment ranks

Description

This function generates a scatter plot or biplot of P-scores with an overlay describing partial order of treatment ranks.

Usage

```

## S3 method for class 'netposet'
plot(
  x,
  plottype = "scatter",
  pooled = ifelse(x$random, "random", "common"),
  dim = "2d",
  sel.x = 1,
  sel.y = 2,
  sel.z = 3,
  cex = 1,

```

```

col = "black",
cex.text = cex,
col.text = col,
adj.x = 0,
adj.y = 1,
offset.x = 0.005,
offset.y = -0.005,
pch = NULL,
cex.points = cex,
col.points = col,
col.lines = "black",
lty.lines = 1,
lwd.lines = 1,
arrows = FALSE,
length = 0.05,
grid = TRUE,
col.grid = "gray",
lty.grid = 2,
lwd.grid = 1,
...
)

```

Arguments

x	An object of class <code>netmeta</code> (mandatory).
plottype	A character string indicating whether a scatter plot or biplot should be produced, either "scatter" or "biplot". Can be abbreviated.
pooled	A character string indicating whether scatter plot should be drawn for common ("common") or random effects model ("random"). Can be abbreviated.
dim	A character string indicating whether a 2- or 3-dimensional plot should be produced, either "2d" or "3d". Can be abbreviated.
sel.x	A numeric specifying number of outcome to use for the x-axis in a scatterplot (argument is not considered for a biplot).
sel.y	A numeric specifying number of outcome to use for the y-axis in a scatterplot (argument is not considered for a biplot).
sel.z	A numeric specifying number of outcome to use for the z-axis in a scatterplot (argument is not considered for a biplot).
cex	The magnification to be used for treatment labels and points.
col	Colour(s) of treatment labels and points.
cex.text	The magnification to be used for treatment labels.
col.text	Colour(s) of treatment labels.
adj.x	Value(s) in [0, 1] to specify adjustment of treatment labels on x-axis (only considered in 2-D plots); see text .
adj.y	Value(s) in [0, 1] to specify adjustment of treatment labels on y-axis (only considered in 2-D plots); see text .

offset.x	Offset(s) of treatment labels on x-axis (only considered in 2-D plots).
offset.y	Offset(s) of treatment labels on y-axis (only considered in 2-D plots).
pch	Plot symbol(s) for points; no points printed if equal to NULL.
cex.points	Magnification(s) to be used for points.
col.points	Colour(s) of points.
col.lines	Line colour.
lty.lines	Line type.
lwd.lines	Line width.
arrows	A logical indicating whether arrows should be printed (only considered in 2-D plots).
length	Length of arrows; see arrows .
grid	A logical indicating whether grid lines should be added to plot.
col.grid	Colour of grid lines.
lty.grid	Line type of grid lines.
lwd.grid	Line width of grid lines.
...	Additional graphical arguments.

Details

By default (arguments `plottype = "scatter"` and `dim = "2d"`), a scatter plot is created showing P-scores (see [netrank](#)) for the first two outcomes considered in the generation of a partially ordered set of treatment ranks (using [netposet](#)). In addition to the P-scores, the partially order of treatment ranks is shown as lines connecting treatments which is analogous to a Hasse diagram. If argument `dim = "3d"`, a 3-D scatter plot is generated showing P-scores for the first three outcomes.

To overcome the restriction of two or three dimension, a biplot (Gabriel, 1971) can be generated using argument `plottype = "biplot"`. This is essentially a scatter plot using the first two (`dim = "2d"`) or three (`dim = "3d"`) components in a principal components analysis (using [prcomp](#)). Note, if only two / three outcomes are considered in a `netposet` object, a 2-D / 3-D scatter plot is generated instead of a biplot as a principal component analysis is superfluous in such a situation.

Arguments `sel.x` and `sel.y` can be used to select different outcomes to show on x- and y-axis in a 2-D scatter plot; argument `sel.z` can be used accordingly in a 3-D scatter plot. These arguments are ignored for a biplot.

Note, in order to generate 3-D plots (argument `dim = "3d"`), R package **rgl** is necessary. Note, under macOS the X.Org X Window System must be available (see <https://www.xquartz.org>).

plot.netrank

Plot treatment ranking(s) of network meta-analyses

Description

Produce an image plot of treatment ranking(s) generated with R function netrank.

Usage

```
## S3 method for class 'netrank'  
plot(  
  ...,  
  name,  
  common,  
  random,  
  seq,  
  low = "red",  
  mid = "yellow",  
  high = "green",  
  col = "black",  
  main,  
  main.size = 14,  
  main.col = col,  
  main.face = "bold",  
  legend = TRUE,  
  axis.size = 12,  
  axis.col = col,  
  axis.face = "plain",  
  na.value = "grey50",  
  angle = 45,  
  hjust.x = 1,  
  vjust.x = 1,  
  hjust.y = 1,  
  vjust.y = 0,  
  nchar.trts,  
  digits = 3,  
  fixed,  
  comb.fixed,  
  comb.random,
```

```
warn.deprecated = gs("warn.deprecated")
)
```

Arguments

...	A single netrank object or a list of netrank objects.
name	An optional character vector providing descriptive names for the network meta-analysis objects.
common	A logical indicating whether results for the common effects model should be plotted.
random	A logical indicating whether results for the random effects model should be plotted.
seq	A character or numerical vector specifying the sequence of treatments on the x-axis.
low	A character string defining the colour for a P-score of 0, see scale_fill_gradient2 .
mid	A character string defining the colour for a P-score of 0.5, see scale_fill_gradient2 .
high	A character string defining the colour for a P-score of 1, see scale_fill_gradient2 .
col	Colour of text.
main	Title.
main.size	Font size of title, see element_text .
main.col	Colour of title, see element_text .
main.face	Font face of title, see element_text .
legend	A logical indicating whether a legend should be printed.
axis.size	Font size of axis text, see element_text .
axis.col	Colour of axis text, see element_text .
axis.face	Font face of axis text, see element_text .
na.value	Colour for missing values, see scale_fill_gradient2 .
angle	Angle for text on x-axis, see element_text .
hjust.x	A numeric between 0 and 1 with horizontal justification of text on x-axis, see element_text .
vjust.x	A numeric between 0 and 1 with vertical justification of text on x-axis, see element_text .
hjust.y	A numeric between 0 and 1 with horizontal justification of text on y-axis, see element_text .
vjust.y	A numeric between 0 and 1 with vertical justification of text on y-axis, see element_text .
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
digits	Minimal number of significant digits, see <code>print.default</code> .
fixed	Deprecated argument (replaced by 'common').
comb.fixed	Deprecated argument (replaced by 'common').

`comb.random` Deprecated argument (replaced by `'random'`).
`warn.deprecated` A logical indicating whether warnings should be printed if deprecated arguments are used.

Details

This function produces an image plot of network rankings (Palpacuer et al., 2018, Figure 4). Note, a scatter plot of two network rankings can be generated with [plot.netposet](#).

By default, treatments are ordered by decreasing P-scores of the first network meta-analysis object. Argument `seq` can be used to specify a different treatment order.

Value

A `ggplot2` object or `NULL` if no ranking was conducted.

plot.rankogram

Plot rankograms

Description

This function produces a rankogram, i.e., an image plot of ranking probabilities for all treatments.

Usage

```
## S3 method for class 'rankogram'
plot(
  x,
  type = if (cumulative.rankprob) "step" else "bar",
  pooled = ifelse(x$random, "random", "common"),
  sort = TRUE,
  trts,
  cumulative.rankprob = x$cumulative.rankprob,
  ylim,
  ylab,
  nchar.trts = x$nchar.trts,
  ...
)
```

Arguments

x	An object of class rankogram .
type	A character string specifying whether a "bar" chart, a "line" graph, or "step" functions should be drawn. Can be abbreviated.
pooled	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
sort	A logical indicating whether treatments should be sorted by decreasing SU-CRAs.
trts	Treatment(s) to show in rankogram.
cumulative.rankprob	A logical indicating whether cumulative ranking probabilities should be shown.
ylim	The y limits (min, max) of the plot.
ylab	A label for the y-axis.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
...	Additional graphical arguments (ignored at the moment).

Details

This function produces plots of (cumulative) ranking probabilities for all treatments as a bar graph, a line graph or as step functions (argument type). All plots will be shown in a single figure if R package **gridExtra** is installed. Otherwise, separate figures will be created for treatments.

By default (argument pooled), results for the random effects model are shown if a network meta-analysis was conducted for both the common and random effects model.

Treatments are sorted according to their mean effects if argument sort = TRUE (default). A subset of treatments can be specified using argument trts.

Cumulative ranking probabilities are shown if cumulative.rankprob = TRUE. By default, step functions are shown for cumulative ranking probabilities.

print.decomp.design *Print method for objects of class decomp.design*

Description

Print method for objects of class decomp.design.

Usage

```
## S3 method for class 'decomp.design'
print(
  x,
  digits.Q = gs("digits.Q"),
  showall = FALSE,
  digits.pval.Q = gs("digits.pval.Q"),
  digits.tau2 = gs("digits.tau2"),
  scientific.pval = gs("scientific.pval"),
  big.mark = gs("big.mark"),
  nchar.trts = x$nchar.trts,
  sort = TRUE,
```

```

    legend = gs("legend"),
    ...
)

```

Arguments

x	An object of class <code>decomp.design</code> .
digits.Q	Minimal number of significant digits for Q statistics, see <code>print.default</code> .
showall	A logical indicating whether results should be shown for all designs or only designs contributing to chi-squared statistics (default).
digits.pval.Q	Minimal number of significant digits for p-value of heterogeneity tests, see <code>print.default</code> .
digits.tau2	Minimal number of significant digits for between-study variance, see <code>print.default</code> .
scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
big.mark	A character used as thousands separator.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
sort	A logical indicating whether to sort results by p-values.
legend	A logical indicating whether a legend should be printed.
...	Additional arguments (ignored at the moment).

  text.I2 = gs("text.I2"),
  details.methods = gs("details"),
  legend = gs("legend"),
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

x	An object of class <code>netcomb</code> or <code>summary.netcomb</code> .
common	A logical indicating whether results for the common effects model should be printed.
random	A logical indicating whether results for the random effects model should be printed.
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.

<code>nchar.comps</code>	A numeric defining the minimum number of characters used to create unique names for components.
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .
<code>digits.stat</code>	Minimal number of significant digits for z- or t-value, see <code>print.default</code> .
<code>digits.pval</code>	Minimal number of significant digits for p-value of overall treatment effect, see <code>print.default</code> .
<code>digits.pval.Q</code>	Minimal number of significant digits for p-value of heterogeneity tests, see <code>print.default</code> .
<code>digits.Q</code>	Minimal number of significant digits for heterogeneity statistics, see <code>print.default</code> .
<code>digits.tau2</code>	Minimal number of significant digits for between-study variance, see <code>print.default</code> .
<code>digits.tau</code>	Minimal number of significant digits for square root of between-study variance, see <code>print.default</code> .
<code>digits.I2</code>	Minimal number of significant digits for I-squared statistic, see <code>print.default</code> .
<code>big.mark</code>	A character used as thousands separator.
<code>scientific.pval</code>	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
<code>zero.pval</code>	A logical specifying whether p-values should be printed with a leading zero.
<code>JAMA.pval</code>	A logical specifying whether p-values for test of overall effect should be printed according to JAMA reporting standards.
<code>print.tau2</code>	A logical specifying whether between-study variance τ^2 should be printed.
<code>print.tau</code>	A logical specifying whether τ , the square root of the between-study variance τ^2 , should be printed.
<code>print.Q</code>	A logical value indicating whether to print the results of the test of heterogeneity.
<code>print.I2</code>	A logical specifying whether heterogeneity statistic I^2 should be printed.
<code>print.I2.ci</code>	A logical specifying whether confidence interval for heterogeneity statistic I^2 should be printed.
<code>text.tau2</code>	Text printed to identify between-study variance τ^2 .
<code>text.tau</code>	Text printed to identify τ , the square root of the between-study variance τ^2 .
<code>text.I2</code>	Text printed to identify heterogeneity statistic I^2 .
<code>details.methods</code>	A logical specifying whether details on statistical methods should be printed.
<code>legend</code>	A logical indicating whether a legend should be printed.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments (to catch deprecated arguments).

```

Arguments

x	An object of class netmeta.
common	A logical indicating whether results for the common effects model should be printed.
random	A logical indicating whether results for the random effects model should be printed.
prediction	A logical indicating whether prediction intervals should be printed.
reference.group	Reference treatment.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if reference.group has been specified.
all.treatments	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If backtransf = TRUE, results for sm = "OR" are presented as odds ratios rather than log odds ratios, for example.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
header	A logical indicating whether information on title of meta-analysis, comparison and outcome should be printed at the beginning of the printout.

digits	Minimal number of significant digits, see print.default.
digits.stat	Minimal number of significant digits for tests of overall effect, see print.default.
digits.pval	Minimal number of significant digits for p-value of overall effects, see print.default.
digits.pval.Q	Minimal number of significant digits for p-value of heterogeneity tests, see print.default.
digits.Q	Minimal number of significant digits for heterogeneity statistics, see print.default.
digits.tau2	Minimal number of significant digits for between-study variance, see print.default.
digits.tau	Minimal number of significant digits for square root of between-study variance, see print.default.
digits.I2	Minimal number of significant digits for I-squared statistic, see print.default.
big.mark	A character used as thousands separator.
scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval	A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval	A logical specifying whether p-values for test of overall effect should be printed according to JAMA reporting standards.
print.tau2	A logical specifying whether between-study variance τ^2 should be printed.
print.tau	A logical specifying whether τ , the square root of the between-study variance τ^2 , should be printed.
print.Q	A logical value indicating whether to print the results of the test of heterogeneity.
print.I2	A logical specifying whether heterogeneity statistic I^2 should be printed.
print.I2.ci	A logical specifying whether confidence interval for heterogeneity statistic I^2 should be printed.
text.tau2	Text printed to identify between-study variance τ^2 .
text.tau	Text printed to identify τ , the square root of the between-study variance τ^2 .
text.I2	Text printed to identify heterogeneity statistic I^2 .
details.methods	A logical specifying whether details on statistical methods should be printed.
legend	A logical indicating whether a legend should be printed.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments.

...
)

```

Arguments

x	An object of class <code>summary.netmeta</code> .
sortvar	An optional vector used to sort individual studies (must be of same length as <code>x\$TE</code>).
common	A logical indicating whether results for the common effects model should be printed.
random	A logical indicating whether results for the random effects model should be printed.
prediction	A logical indicating whether prediction intervals should be printed.
reference.group	Reference treatment.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if <code>reference.group</code> has been specified.
all.treatments	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
details	A logical indicating whether further details for individual studies should be printed.

<code>nma</code>	A logical indicating whether summary results of network meta-analysis should be printed.
<code>overall.hetstat</code>	A logical indicating whether to print heterogeneity measures.
<code>backtransf</code>	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>nchar.studlab</code>	A numeric defining the minimum number of characters used to create unique study labels.
<code>digits</code>	Minimal number of significant digits, see <code>print.default</code> .
<code>digits.se</code>	Minimal number of significant digits for standard deviations and standard errors, see <code>print.default</code> .
<code>digits.pval.Q</code>	Minimal number of significant digits for p-value of heterogeneity tests, see <code>print.default</code> .
<code>digits.Q</code>	Minimal number of significant digits for heterogeneity statistics, see <code>print.default</code> .
<code>digits.tau2</code>	Minimal number of significant digits for between-study variance, see <code>print.default</code> .
<code>digits.I2</code>	Minimal number of significant digits for I-squared statistic, see <code>print.default</code> .
<code>big.mark</code>	A character used as thousands separator.
<code>scientific.pval</code>	A logical specifying whether p-values should be printed in scientific notation, e.g., <code>1.2345e-01</code> instead of <code>0.12345</code> .
<code>zero.pval</code>	A logical specifying whether p-values should be printed with a leading zero.
<code>JAMA.pval</code>	A logical specifying whether p-values for test of overall effect should be printed according to JAMA reporting standards.
<code>print.tau2</code>	A logical specifying whether between-study variance τ^2 should be printed.
<code>print.tau</code>	A logical specifying whether τ , the square root of the between-study variance τ^2 , should be printed.
<code>print.Q</code>	A logical value indicating whether to print the results of the test of heterogeneity.
<code>print.I2</code>	A logical specifying whether heterogeneity statistic I^2 should be printed.
<code>print.I2.ci</code>	A logical specifying whether confidence interval for heterogeneity statistic I^2 should be printed.
<code>truncate</code>	An optional vector used to truncate the printout of results for individual studies (must be a logical vector of length corresponding to the number of pairwise comparisons <code>x\$TE</code> or contain numerical values).
<code>text.truncate</code>	A character string printed if study results were truncated from the printout.
<code>details.methods</code>	A logical specifying whether details on statistical methods should be printed.
<code>legend</code>	A logical indicating whether a legend should be printed.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments.

radial.netmeta	<i>'Comparison-adjusted' radial plot</i>
----------------	--

Description

Draw a 'comparison-adjusted' radial plot to assess funnel plot asymmetry in network meta-analysis.

Usage

```
## S3 method for class 'netmeta'
radial(
  x,
  order,
  pooled = ifelse(x$random, "random", "common"),
  level = x$level,
  pch,
  col = "black",
  legend = FALSE,
  pos.legend = "topright",
  pos.tests = "topleft",
  lump.comparator = FALSE,
  text.comparator = "comparator",
  method.bias,
  text.linreg = "(Egger)",
  text.rank = "(Begg-Mazumdar)",
  text.mm = "(Thompson-Sharp)",
  sep.trts = x$sep.trts,
  nchar.trts = x$nchar.trts,
  digits.pval = gs("digits.pval"),
  warn.deprecated = gs("warn.deprecated"),
  linreg = FALSE,
  rank = FALSE,
  mm = FALSE,
  ...
)
```

Arguments

<code>x</code>	An object of class <code>netmeta</code> .
<code>order</code>	A mandatory character or numerical vector specifying the order of treatments or list of comparators (see <code>Details</code>).
<code>pooled</code>	A character string indicating whether results for the common ("common") or random effects model ("random") should be plotted. Can be abbreviated.
<code>level</code>	The confidence level utilised in the plot.
<code>pch</code>	The plotting symbol(s) used for individual studies within direct comparisons.
<code>col</code>	The colour(s) used for individual studies within direct comparisons.
<code>legend</code>	A logical indicating whether a legend with information on direct comparisons should be added to the plot.
<code>pos.legend</code>	The position of the legend describing plotting symbols and colours for direct comparisons.
<code>pos.tests</code>	The position of results for test(s) of funnel plot asymmetry.
<code>lump.comparator</code>	A logical indicating whether comparators should be lumped, e.g., to specify inactive treatments. information on direct comparisons should be added to the plot.
<code>text.comparator</code>	A character string used in the plot to label the comparator if <code>lump.comparator</code> is TRUE.
<code>method.bias</code>	A character vector indicating which test(s) for funnel plot asymmetry to use. Admissible values are "Begg", "Egger", and "Thompson", can be abbreviated. See function metabias .
<code>text.linreg</code>	A character string used in the plot to label the Egger test for funnel plot asymmetry.
<code>text.rank</code>	A character string used in the plot to label the Begg test for funnel plot asymmetry.
<code>text.mm</code>	A character string used in the plot to label the Thompson-Sharp test for funnel plot asymmetry.
<code>sep.trts</code>	A character used in comparison names as separator between treatment labels.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names (see netmeta).
<code>digits.pval</code>	Minimal number of significant digits for p-value of test(s) for funnel plot asymmetry.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>linreg</code>	Deprecated argument (replaced by <code>method.bias</code>).
<code>rank</code>	Deprecated argument (replaced by <code>method.bias</code>).
<code>mm</code>	Deprecated argument (replaced by <code>method.bias</code>).
<code>...</code>	Additional graphical arguments passed as arguments to radial.meta .

Details

A ‘comparison-adjusted’ radial plot is drawn in the active graphics window. The idea of this radial plot is similar to a ‘comparison-adjusted’ funnel plot (Chaimani & Salanti, 2012).

Argument order is mandatory to determine the order of treatments (Chaimani et al., 2013):

“Before using this plot, investigators should order the treatments in a meaningful way and make assumptions about how small studies differ from large ones. For example, if they anticipate that newer treatments are favored in small trials, then they could name the treatments from oldest to newest so that all comparisons refer to ‘old versus new intervention’. Other possibilities include defining the comparisons so that all refer to an active treatment versus placebo or sponsored versus non-sponsored intervention.”

Alternatively, it is possible to only provide a single or few treatment name(s) in argument order to define the comparator(s). In this case only comparisons with this / these treatment(s) will be considered. If argument `lump.comparator` is TRUE, all comparators will be lumped into a single group. The text for this group can be specified with argument `text.comparator`.

Value

A data frame with the following columns:

<code>studlab</code>	Study label.
<code>treat1</code>	Label/Number for first treatment.
<code>treat2</code>	Label/Number for second treatment.
<code>comparison</code>	Treatment comparison.
<code>TE</code>	Estimate of treatment effect, e.g., log odds ratio.
<code>TE.direct</code>	Pooled estimate from direct evidence.
<code>TE.adj</code>	‘Comparison-adjusted’ treatment effect (TE - TE.direct).
<code>seTE</code>	Standard error of treatment estimate.
<code>pch</code>	Plotting symbol(s).
<code>col</code>	Colour of plotting symbol(s).

rankogram	<i>Generic function for rankograms</i>
-----------	--

Description

Generic function to calculate the probabilities of each treatment being at each possible rank and the SUCRAs (Surface Under the Cumulative RAnking curve) in network meta-analysis.

Usage

```
rankogram(x, ...)
```

Arguments

x	An R object.
...	Additional arguments.

Details

For more details, look at the following functions to generate rankograms:

- [rankogram.netmeta](#)
- [rankogram.default](#)

Author(s)

Guido Schwarzer <guido.schwarzer@uniklinik-freiburg.de>

```

rankogram.default *Calculate rankogram from treatment effect samples*

Description

This function calculates the probabilities of each treatment being at each possible rank and the SUCRAs (Surface Under the Cumulative RAnking curve) from a sample of treatment estimates in network meta-analysis.

Usage

```
## Default S3 method:
rankogram(
  x,
  pooled = "unspecified",
  small.values = "desirable",
  cumulative.rankprob = FALSE,
  keep.samples = FALSE,
  nchar.trts = gs("nchar.trts"),
  ...
)
```

Arguments

<code>x</code>	A matrix or data frame with treatment effects in columns and samples in rows.
<code>pooled</code>	A character string indicating whether samples come from a common ("common"), random effects ("random"), or "unspecified" model, can be abbreviated.
<code>small.values</code>	An optional character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect, can be abbreviated.
<code>cumulative.rankprob</code>	A logical indicating whether cumulative ranking probabilities should be printed.
<code>keep.samples</code>	A logical indicating whether to keep the generated samples.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>...</code>	Additional arguments (ignored).

Details

We derive a matrix showing the probability of each treatment being at each possible rank. To this aim, we use samples and summarise them using the ranking metric SUCRAs (Surface Under the Cumulative RAnking curve).

The matrix / data frame in argument `x` must contain the sampled effects for each treatment.

Value

An object of class rankogram with corresponding print and plot function. The object is a list containing the following components:

```

ranking.matrix.common
    Numeric matrix giving the probability of each treatment being at each possible
    rank for the common effects model.
ranking.common
    SUCRA values for the common effects model.
ranking.matrix.random
    Numeric matrix giving the probability of each treatment being at each possible
    rank for the random effects model.
ranking.random
    SUCRA values for the random effects model.
cumrank.matrix.common
    Numeric matrix giving the cumulative ranking probability of each treatment for
    the common effects model.
cumrank.matrix.random
    Numeric matrix giving the cumulative ranking probability of each treatment for
    the random effects model.
nsim, common, random
    As defined above
,
small.values, x
    As defined above
,

```

Examples

```

pw1 <- pairwise(treatment, event = r, n = N, studlab = author,
  data = dat.woods2010, sm = "OR")
net1 <- netmeta(pw1, small.values = "desirable")

set.seed(1909) # get reproducible results
ran1 <- rankogram(net1, common = FALSE, nsim = 10, # reduce runtime
  keep.samples = TRUE)

```

```

ran1
rankogram(ran1$samples.random)

```

```

rankogram.netmeta    Calculate rankogram

```

Description

This function calculates the probabilities of each treatment being at each possible rank and the SUCRAs (Surface Under the Cumulative RANking curve) in frequentist network meta-analysis.

Usage

```

## S3 method for class 'netmeta'
rankogram(
  x,
  nsim = gs("nsim"),
  common = x$common,
  random = x$random,
  small.values = x$small.values,
  cumulative.rankprob = FALSE,
  keep.samples = FALSE,
  nchar.trts = x$nchar.trts,
  warn.deprecated = gs("warn.deprecated"),
  ...
)

```

Arguments

<code>x</code>	An object of class netmeta .
<code>nsim</code>	Number of simulations.
<code>common</code>	A logical indicating to compute ranking probabilities and SUCRAs for the common effects model.
<code>random</code>	A logical indicating to compute ranking probabilities and SUCRAs for the random effects model.
<code>small.values</code>	A character string specifying whether small treatment effects indicate a beneficial ("desirable") or harmful ("undesirable") effect, can be abbreviated.
<code>cumulative.rankprob</code>	A logical indicating whether cumulative ranking probabilities should be printed.
<code>keep.samples</code>	A logical indicating whether to keep the generated samples.
<code>nchar.trts</code>	A numeric defining the minimum number of characters used to create unique treatment names.
<code>warn.deprecated</code>	A logical indicating whether warnings should be printed if deprecated arguments are used.
<code>...</code>	Additional arguments (ignored).

Details

We derive a matrix showing the probability of each treatment being at each possible rank. To this aim, we use resampling from a multivariate normal distribution with estimated network effects as means and corresponding estimated variance covariance matrix. We then summarise them using the ranking metric SUCRA (Surface Under the Cumulative RAnking curve).

Value

An object of class rankogram with corresponding print and plot function. The object is a list containing the following components:

```

ranking.matrix.common
    Numeric matrix giving the probability of each treatment being at each possible
    rank for the common effects model.
ranking.common SUCRA values for the common effects model.
ranking.matrix.random
    Numeric matrix giving the probability of each treatment being at each possible
    rank for the random effects model.
ranking.random SUCRA values for the random effects model.
cumrank.matrix.common
    Numeric matrix giving the cumulative ranking probability of each treatment for
    the common effects model.
cumrank.matrix.random
    Numeric matrix giving the cumulative ranking probability of each treatment for
    the random effects model.
nsim, common, random
    As defined above
,
small.values, x As defined above
,

```

Senn2013

*Network meta-analysis in diabetes***Description**

Network meta-analysis in diabetes comparing effects of a number of drugs on the HbA1c value.

These data are used as an example in Senn et al. (2013) and have been preprocessed for use in R package netmeta.

Format

A data frame with the following columns:

<i>TE</i>	treatment effect
<i>seTE</i>	standard error of treatment effect
<i>treat1</i>	treatment 1
<i>treat2</i>	treatment 2
<i>treat1.long</i>	treatment 1 (full treatment names)
<i>treat2.long</i>	treatment 2 (full treatment names)
<i>studlab</i>	Study label

Details

Treatment labels provided by columns treat1 and treat2 have been abbreviated:

- acar = Acarbose
- benf = Benfluorex
- metf = Metformin
- migl = Miglitol
- piog = Pioglitazone

- plac = Placebo
- rosi = Rosiglitazone
- sita = Sitagliptin
- sulf = Sulfonylurea
- vild = Vildagliptin

Full treatment names are available in columns `treat1.long` and `treat2.long`.

`smokingcessation`*Network meta-analysis of interventions for smoking cessation*

Description

Network meta-analysis comparing the effects of a number of interventions for smoking cessation.

These data are used as an example in Dias et al. (2013), page 651.

Format

A data frame with the following columns:

<i>event1</i>	number of individuals with successful smoking cessation in arm 1
<i>n1</i>	number of individuals in arm 1
<i>event2</i>	number of individuals with successful smoking cessation in arm 2
<i>n2</i>	number of individuals in arm 2
<i>event3</i>	number of individuals with successful smoking cessation in arm 3
<i>n3</i>	number of individuals in arm 3

Stowe2010 *Network meta-analysis of adjuvant treatments to levodopa therapy for Parkinson's disease*

Description

This dataset contains data from a Cochrane review assessing efficacy and safety of three drug classes as adjuvant treatment to levodopa therapy in patients with Parkinson's disease and motor complications (Stowe et al., 2010). The authors conducted three pairwise meta-analyses comparing dopamine agonists, catechol-O-methyl transferase inhibitors (COMTIs), and monoamine oxidase type B inhibitors (MAOBIs), respectively, with placebo.

The primary outcome was the mean reduction of the time spent in a relatively immobile 'off' phase (mean off-time), calculated in hours per day. Relative treatment effects were expressed as mean difference. Data on this outcome were available for 5,331 patients from 28 studies comparing an active treatment with placebo and one three-arm study comparing two active treatments with placebo.

Format

A data frame with the following columns:

<i>study</i>	study label
<i>id</i>	study id
<i>t1</i>	treatment 1
<i>y1</i>	treatment effect arm 1
<i>sd1</i>	Standard deviation arm 1
<i>n1</i>	Sample size arm 1
<i>t2</i>	treatment 2
<i>y2</i>	treatment effect arm 2
<i>sd2</i>	Standard deviation arm 2
<i>n2</i>	Sample size arm 2
<i>t3</i>	treatment 3
<i>y3</i>	treatment effect arm 3
<i>sd3</i>	Standard deviation arm 3
<i>n3</i>	Sample size arm 3

Note

The dataset Stowe2010 is identical to dataset [dat.stowe2010](#) in R package **metadat**.

print.se = !backtransf,
print.tau2 = gs("print.tau2"),
print.tau = gs("print.tau"),
print.Q = gs("print.Q"),
text.tau2 = gs("text.tau2"),
text.tau = gs("text.tau"),
details.methods = gs("details"),
legend = gs("legend"),
...
)

```

Arguments

x	An object of class <code>netmeta</code> (or <code>subgroup.netmeta</code>).
subgroup	A vector defining the subgroups considered in the network meta-analysis.
only.connected	A logical indicating whether networks of subgroups must be connected.
common	A logical indicating whether results for common effect subgroup network meta-analysis should be printed.
random	A logical indicating whether results for random effects subgroup network meta-analysis should be printed.
method.tau	A character string indicating which method is used to estimate the between-study variance τ^2 and its square root τ . Either "DL", "REML", or "ML", can be abbreviated.
level.ma	The level used to calculate confidence intervals for network estimates.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots. If <code>backtransf = TRUE</code> , results for <code>sm = "OR"</code> are presented as odds ratios rather than log odds ratios, for example.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names (see netmeta).
...	Additional arguments.
digits	Minimal number of significant digits, see <code>print.default</code> .
digits.se	Minimal number of significant digits for standard errors.
digits.Q	Minimal number of significant digits for heterogeneity statistic Q, see <code>print.default</code> .
digits.pval.Q	Minimal number of significant digits for p-value of heterogeneity test, see <code>print.default</code> .
digits.tau2	Minimal number of significant digits for between-study variance τ^2 , see <code>print.default</code> .
digits.tau	Minimal number of significant digits for τ , the square root of the between-study variance τ^2 .
big.mark	A character used as thousands separator.

scientific.pval	A logical specifying whether p-values should be printed in scientific notation, e.g., 1.2345e-01 instead of 0.12345.
zero.pval	A logical specifying whether p-values should be printed with a leading zero.
JAMA.pval	A logical specifying whether p-values for test of overall effect should be printed according to JAMA reporting standards.
print.se	A logical specifying whether standard errors should be printed.
print.tau2	A logical specifying whether between-study variance τ^2 should be printed.
print.tau	A logical specifying whether τ , the square root of the between-study variance τ^2 , should be printed.
print.Q	A logical value indicating whether to print the results of the test of heterogeneity.
text.tau2	Text printed to identify between-study variance τ^2 .
text.tau	Text printed to identify τ , the square root of the between-study variance τ^2 .
details.methods	A logical specifying whether details on statistical methods should be printed.
legend	A logical indicating whether a legend should be printed.

Value

An object of class "subgroup.netmeta" with corresponding print and forest function.

See Also

[forest.subgroup.netmeta](#), [forest.netmeta](#)

Examples

```
data("Senn2013")
# Add variable with (fictitious) risk of bias values
Senn2013$rob <- NA
set.seed(1909)
for (i in unique(Senn2013$studlab))
  Senn2013$rob[Senn2013$studlab == i] <- sample(1:3, 1)
Senn2013$rob <- factor(Senn2013$rob, levels = 1:3,
  labels = c("low", "moderate", "high"))
# Conduct network meta-analysis
net <- netmeta(TE, seTE, treat1.long, treat2.long, studlab,
  data = Senn2013, sm = "MD", reference = "plac", nchar.trts = 4)
# Conduct subgroup network meta-analysis
subgroup(net, rob, common = FALSE)
```

summary.netcomb	<i>Summary method for objects of class netcomb</i>
-----------------	--

Description

Summary method for objects of class netcomb.

Usage

```
## S3 method for class 'netcomb'
summary(
  object,
  common = object$common,
  random = object$random,
  overall.hetstat = object$overall.hetstat,
  backtransf = object$backtransf,
  nchar.comps = object$nchar.comps,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

object	An object of class netcomb.
common	A logical indicating whether results for the common effects model should be printed.
random	A logical indicating whether results for the random effects model should be printed.
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots.
nchar.comps	A numeric defining the minimum number of characters used to create unique component names.
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).

Value

A list of class "summary.netcomb" is returned with the following elements:

k	Total number of studies.
m	Total number of pairwise comparisons.

n	Total number of treatments.
d	Total number of designs (corresponding to the unique set of treatments compared within studies).
c	Total number of components.
s	Total number of subnetworks (for <code>discomb</code>).
trts	Treatments included in network meta-analysis.
k.trts	Number of studies evaluating a treatment.
n.trts	Number of observations receiving a treatment (if available).
events.trts	Number of events observed for a treatment (if available).
studies	Study labels coerced into a factor with its levels sorted alphabetically.
narms	Number of arms for each study.
designs	Vector with unique designs present in the network. A design corresponds to the set of treatments compared within a study.
comps	Components included in network meta-analysis.
k.comps	Number of studies evaluating a component.
n.comps	Number of observations receiving a component (if available).
events.comps	Number of events observed for a component (if available).
comparison	Results for pairwise comparisons (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code>).
comparison.nma.common	Results for pairwise comparisons based on common effects NMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code> , <code>leverage</code>).
comparison.nma.random	Results for pairwise comparisons based on random effects NMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code>).
comparison.cnma.common	Results for pairwise comparisons based on common effects CNMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code> , <code>leverage</code>).
comparison.cnma.random	Results for pairwise comparisons based on random effects CNMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code>).
components.common	Results for components based on common effects CNMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code> , <code>leverage</code>).
components.random	Results for components based on random effects CNMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code>).
combinations.common	Results for available combinations based on common effects CNMA model (data frame with columns <code>studlab</code> , <code>treat1</code> , <code>treat2</code> , <code>TE</code> , <code>seTE</code> , <code>lower</code> , <code>upper</code> , <code>z</code> , <code>p</code> , <code>leverage</code>).

combinations.random	Results for available combinations based on random effects CNMA model (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p).
common	Results for common effects model (a list with elements TE, seTE, lower, upper, z, p).
random	Results for random effects model (a list with elements TE, seTE, lower, upper, z, p).
predict	Prediction intervals (a list with elements seTE, lower, upper).
Q.additive	Overall heterogeneity / inconsistency statistic.
df.Q.additive	Degrees of freedom for test of heterogeneity / inconsistency.
pval.Q.additive	P-value for test of heterogeneity / inconsistency.
I2, lower.I2, upper.I2	I-squared, lower and upper confidence limits.
tau	Square-root of between-study variance.
Q.additive	Overall heterogeneity / inconsistency statistic (CNMA model).
df.Q.additive	Degrees of freedom for test of heterogeneity / inconsistency (CNMA model).
pval.Q.additive	P-value for test of heterogeneity / inconsistency (CNMA model).
Q.standard	Overall heterogeneity statistic (NMA model).
df.Q.heterogeneity	Degrees of freedom for test of overall heterogeneity (NMA model).
pval.Q.heterogeneity	P-value for test of overall heterogeneity (NMA model).
Q.diff	Q statistic for difference between CNMA and NMA model.
df.Q.diff, pval.Q.diff	Corresponding degrees of freedom and p-value.
sm	A character string indicating underlying summary measure.
method	A character string indicating which method is to be used for pooling of studies.
level	The level used to calculate confidence intervals for individual studies.
level.ma	The level used to calculate confidence intervals for pooled estimates.
ci.lab	Label for confidence interval.
reference.group, baseline.reference	As defined above.
all.treatments	As defined above.
seq	A character specifying the sequence of treatments.
tau.preset	An optional value for the square-root of the between-study variance τ^2 .
sep.comps	A character used in comparison names as separator between component labels.
nchar.comps	A numeric defining the minimum number of characters used to create unique component names.

overall.hetstat, backtransf
 As defined above.

title Title of meta-analysis / systematic review.

x [netmeta](#) object (if available).

call Function call.

version Version of R package **netmeta** used to create object.

```

summary.netmeta

*Summary method for objects of class netmeta***Description**

Summary method for objects of class netmeta.

Usage

```
## S3 method for class 'netmeta'
summary(
  object,
  common = object$common,
  random = object$random,
  prediction = object$prediction,
  reference.group = object$reference.group,
  baseline.reference = object$baseline.reference,
  all.treatments = object$all.treatments,
  overall.hetstat = object$overall.hetstat,
  backtransf = object$backtransf,
  nchar.trts = object$nchar.trts,
  warn.deprecated = gs("warn.deprecated"),
  ...
)
```

Arguments

object	An object of class netmeta.
common	A logical indicating whether results for the common effects model should be printed.

random	A logical indicating whether results for the random effects model should be printed.
prediction	A logical indicating whether prediction intervals should be printed.
reference.group	Reference treatment.
baseline.reference	A logical indicating whether results should be expressed as comparisons of other treatments versus the reference treatment (default) or vice versa. This argument is only considered if reference.group has been specified.
all.treatments	A logical or "NULL". If TRUE, matrices with all treatment effects, and confidence limits will be printed.
overall.hetstat	A logical indicating whether to print heterogeneity measures.
backtransf	A logical indicating whether results should be back transformed in printouts and forest plots.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names (see Details).
warn.deprecated	A logical indicating whether warnings should be printed if deprecated arguments are used.
...	Additional arguments (to catch deprecated arguments).

Value

A list of class "summary.netmeta" is returned with the following elements:

k	Total number of studies.
m	Total number of pairwise comparisons.
n	Total number of treatments.
d	Total number of designs (corresponding to the unique set of treatments compared within studies).
trts	Treatments included in network meta-analysis.
k.trts	Number of studies evaluating a treatment.
n.trts	Number of observations receiving a treatment (if available).
events.trts	Number of events observed for a treatment (if available).
studies	Study labels coerced into a factor with its levels sorted alphabetically.
narms	Number of arms for each study.
designs	Vector with unique designs present in the network. A design corresponds to the set of treatments compared within a study.
comparisons	Vector with unique direct comparisons present in the network.
comparison	Results for pairwise comparisons (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p).

comparison.nma.common	Results for pairwise comparisons based on common effects model (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p, leverage).
comparison.nma.random	Results for pairwise comparisons based on random effects model (data frame with columns studlab, treat1, treat2, TE, seTE, lower, upper, z, p).
common	Results for common effects model (a list with elements TE, seTE, lower, upper, z, p).
random	Results for random effects model (a list with elements TE, seTE, lower, upper, z, p).
predict	Prediction intervals (a list with elements seTE, lower, upper).
Q	Overall heterogeneity / inconsistency statistic.
df.Q	Degrees of freedom for test of heterogeneity / inconsistency.
pval.Q	P-value for test of heterogeneity / inconsistency.
I2, lower.I2, upper.I2	I-squared, lower and upper confidence limits.
tau	Square-root of between-study variance.
Q.heterogeneity	Overall heterogeneity statistic.
df.Q.heterogeneity	Degrees of freedom for test of overall heterogeneity.
pval.Q.heterogeneity	P-value for test of overall heterogeneity.
Q.inconsistency	Overall inconsistency statistic.
df.Q.inconsistency	Degrees of freedom for test of overall inconsistency.
pval.Q.inconsistency	P-value for test of overall inconsistency.
Q.decomp	Data frame with columns 'treat1', 'treat2', 'Q', 'df' and 'pval.Q', providing heterogeneity statistics for each pairwise meta-analysis of direct comparisons.
sm	A character string indicating underlying summary measure.
method	A character string indicating which method is to be used for pooling of studies.
level	The level used to calculate confidence intervals for individual studies.
level.ma	The level used to calculate confidence intervals for pooled estimates.
level.predict	The level used to calculate prediction intervals for a new study.
ci.lab	Label for confidence interval.
incr	Numerical value added to cell frequencies (if applicable).
method.incr	A character string indicating which continuity correction method was used (if applicable).
allstudies	A logical indicating whether studies with zero events or non-events in all treatment arms should be included in an inverse variance meta-analysis (if applicable).

cc.pooled	A logical indicating whether incr should be used as a continuity correction (if applicable).
reference.group, baseline.reference	As defined above.
all.treatments	As defined above.
seq	A character specifying the sequence of treatments.
tau.preset	An optional value for the square-root of the between-study variance τ^2 .
sep.trts	A character used in comparison names as separator between treatment labels.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
prediction, overall.hetstat, backtransf	As defined above.
title	Title of meta-analysis / systematic review.
call	Function call.
version	Version of R package netmeta used to create object.

summary.netmetareg *Summary method for objects of class netmetareg*

Description

Summary method for objects of class netmetareg to print list of studies in subnetworks.

Usage

```
## S3 method for class 'netmetareg'
summary(object, ...)

## S3 method for class 'summary.netmetareg'
print(
  x,
  digits = gs("digits"),
```

```

    digits.se = gs("digits.se"),
    big.mark = gs("big.mark"),
    ...
  )

```

Arguments

object	An object of class netmetareg.
...	Additional arguments (ignored).
x	An object of class summary.netmetareg.
digits	Minimal number of significant digits, see print.default.
digits.se	Minimal number of significant digits for standard errors.
big.mark	A character used as thousands separator.

  digits = gs("digits.prop"),
  digits.mean = 2,
  details.methods = gs("details"),
  legend = gs("legend"),
  ...
)
```

Arguments

object	An object of class rankogram.
...	Additional arguments (passed on to print.rankogram).
x	An object of class summary.rankogram.
common	A logical indicating to print ranking probabilities and SUCRAs for the common effects model.
random	A logical indicating to print ranking probabilities and SUCRAs for the random effects model.
sort	A logical indicating whether treatments should be sorted by decreasing SUCRAs.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
digits	Minimal number of significant digits for ranking probabilities and SUCRAs, see print.default .
digits.mean	Minimal number of significant digits for mean ranks, see print.default .
details.methods	A logical specifying whether details on statistical methods should be printed.
legend	A logical indicating whether a legend should be printed.

```

treats	<i>Abbreviate treatment names</i>
--------	-----------------------------------

Description

Auxiliary functions to create uniquely abbreviated treatment names.

Usage

```
treats(x, nchar.trts = 8, row = TRUE)

comps(x, trts, sep.trts, nchar.trts = 8, row = TRUE)
```

Arguments

x	A vector with treatment or comparison names or a matrix with treatment or comparison names as row and / or column names.
nchar.trts	A numeric defining the minimum number of characters used to create unique treatment names.
row	A logical indicating whether row or column names should be used (only considered if argument x is a matrix).
trts	A character vector with treatment names.
sep.trts	A character used in comparison names as separator between treatment labels.

Details

These auxiliary functions can be used to create uniquely abbreviated treatment names (and are used internally in several R functions for this purpose).

In order to construct uniquely abbreviated treatment names, `treats` uses [substring](#) to extract the first `nchar.trts` characters. If these abbreviated treatment names are not unique, [abbreviate](#) with argument `minlength = nchar.trts` is used.

In order to construct comparisons with uniquely abbreviated treatment names, `comps` calls `treats` internally.

Examples

```
data(Senn2013)
#
net1 <- netmeta(TE, seTE, treat1.long, treat2.long, studlab,
  data = Senn2013)

# Full treatment names
#
net1$trts

# Treatment names with four characters
#
treats(net1$trts, nchar.trts = 4)

# With two characters
#
treats(net1$trts, nchar.trts = 2)

# With one character (if possible)
#
treats(net1$trts, nchar.trts = 1)

# Full comparison names
#
net1$comparisons

# Abbreviated comparison names
#
with(net1, comps(comparisons, trts, sep.trts, nchar = 4))
```

Description

Count mortality statistics in randomised controlled trials of treatments for chronic obstructive pulmonary disease (Woods et al. (2010), Table 1).

Format

A data frame with the following columns:

<i>author</i>	first author / study name
<i>treatment</i>	treatment
<i>r</i>	number of deaths in treatment arm
<i>N</i>	number of patients in treatment arm

Note

The dataset Woods2010 is identical to dataset [dat.woods2010](#) in R package **metadat**.
