1 Introduction

\LaTeX{} 2 was released in 1994 and added a number of then-new concepts to \LaTeX{}. For package and class authors, these are described in the document \texttt{clsguide-historic}, which has largely remained unchanged. Since then, the \LaTeX{} team have worked on a number of ideas, firstly a programming language for \LaTeX{} (L3 programming layer) and then a range of tools for authors which build on that language. Here, we describe the current, stable set of tools provided by the \LaTeX{} kernel for package and class developers. We assume familiarity with general \LaTeX{} usage as a document author, and that the material here is read in conjunction with \texttt{usrguide}, which provides information for general \LaTeX{} users on up-to-date approaches to creating commands, etc.

2 Writing classes and packages

This section covers some general points concerned with writing \LaTeX{} classes and packages.

2.1 Is it a class or a package?

The first thing to do when you want to put some new \LaTeX{} commands in a file is to decide whether it should be a \textit{document class} or a \textit{package}. The rule of thumb is:

If the commands could be used with any document class, then make them a package; and if not, then make them a class.

There are two major types of class: those like \texttt{article}, \texttt{report} or \texttt{letter}, which are free-standing; and those which are extensions or variations of other classes—for example, the \texttt{proc} document class, which is built on the \texttt{article} document class.
Thus, a company might have a local *ownlet* class for printing letters with their own headed note-paper. Such a class would build on top of the existing *letter* class but it cannot be used with any other document class, so we have *ownlet.cls* rather than *ownlet.sty*.

The *graphics* package, in contrast, provides commands for including images into a \LaTeX{} document. Since these commands can be used with any document class, we have *graphics.sty* rather than *graphics.cls*.

### 2.2 Using ‘docstrip’ and ‘doc’

If you are going to write a large class or package for \LaTeX{} then you should consider using the *doc* software which comes with \LaTeX{}. \LaTeX{} classes and packages written using this can be processed in two ways: they can be run through \LaTeX{}, to produce documentation; and they can be processed with *docstrip*, to produce the .cls or .sty file.

The *doc* software can automatically generate indexes of definitions, indexes of command use, and change-log lists. It is very useful for maintaining and documenting large \TeX{} sources.

The documented sources of the \LaTeX{} kernel itself, and of the standard classes, etc., are *doc* documents; they are in the .dtx files in the distribution. You can, in fact, typeset the source code of the kernel as one long document, complete with index, by running \LaTeX{} on *source2e.tex*. Typesetting these documents uses the class file *ltxdoc.cls*.

For more information on *doc* and *docstrip*, consult the files *docstrip.dtx*, *doc.dtx*, and *The \LaTeX{} Companion*. For examples of its use, look at the .dtx files.

### 2.3 Policy on standard classes

Many of the problem reports we receive concerning the standard classes are not concerned with bugs but are suggesting, more or less politely, that the design decisions embodied in them are ‘not optimal’ and asking us to modify them.

There are several reasons why we should not make such changes to these files.

- However misguided, the current behavior is clearly what was intended when these classes were designed.
- It is not good practice to change such aspects of ‘standard classes’ because many people will be relying on them.

We have therefore decided not to even consider making such modifications, nor to spend time justifying that decision. This does not mean that we do not agree that there are many deficiencies in the design of these classes, but we have many tasks with higher priority than continually explaining why the standard classes for \LaTeX{} cannot be changed.

We would, of course, welcome the production of better classes, or of packages that can be used to enhance these classes. So your first thought when you consider such a deficiency will, we hope, be “what can I do to improve this?”
2.4 Command names

Prior to the introduction of the L3 programming layer described in the next section, \LaTeX{} had three types of command.

There are the author commands, such as \texttt{\textbackslash section}, \texttt{\textbackslash emph} and \texttt{\textbackslash times}: most of these have short names, all in lower case.

There are also the class and package writer commands: most of these have long mixed-case names such as the following.

\texttt{\textbackslash InputIfFileExists \textbackslash RequirePackage \textbackslash PassOptionsToClass}

Finally, there are the internal commands used in the \LaTeX{} implementation, such as \texttt{\textbackslash @tempcnta}, \texttt{\textbackslash @ifnextchar} and \texttt{\textbackslash @eha}: most of these commands contain @ in their name, which means they cannot be used in documents, only in class and package files.

Unfortunately, for historical reasons the distinction between these commands is often blurred. For example, \texttt{\textbackslash hbox} is an internal command which should only be used in the \LaTeX{} kernel, whereas \texttt{\textbackslash @x} is the constant $-1$ and could have been \texttt{\textbackslash MinusOne}.

However, this rule of thumb is still useful: if a command has @ in its name then it is not part of the supported \LaTeX{} language—and its behavior may change in future releases! If a command is mixed-case, or is described in \LaTeX{}: A Document Preparation System, then you can rely on future releases of \LaTeX{} supporting the command.

2.5 Programming support

As noted in the introduction, the \LaTeX{} kernel today loads dedicated support from programming, here referred to as the L3 programming layer but also often called expl3. Details of the general approach taken by the L3 programming layer are given in the document expl3, while a reference for all current code interfaces is available as interface3. This layer contains two types of command: a documented set of commands making up the API and a large number of private internal commands. The latter all start with two underscores and should not be used outside of the code module which defines them. This more structured approach means that using the L3 programming layer does not suffer from the somewhat fluid situation mentioned above with ‘@ commands’.

We do not cover the detail of using the L3 programming layer here. A good introduction to the approach is provided at \url{https://www.alanshawn.com/latex3-tutorial/}.

2.6 Box commands and color

Even if you do not intend to use color in your own documents, by taking note of the points in this section you can ensure that your class or package is compatible
with the color package. This may benefit people using your class or package and wish to use color.

The simplest way to ensure ‘color safety’ is to always use \LaTeX box commands rather than \TeX primitives, that is use \verb|\sbox| rather than \verb|\setbox|, \verb|\mbox| rather than \verb|\hbox| and \verb|\parbox| or the \verb|minipage| environment rather than \verb|\vbox|. The \LaTeX box commands have new options which mean that they are now as powerful as the \TeX primitives.

As an example of what can go wrong, consider that in \{\ttfamily <text>\} the font is restored just before the \}, whereas in the similar looking construction \{	extcolor{green} <text>\} the color is restored just after the final \}. Normally this distinction does not matter at all; but consider a primitive \TeX box assignment such as:

\begin{verbatim}
\setbox0=\hbox{\textcolor{green} <text>}
\end{verbatim}

Now the color-restore occurs after the \} and so is not stored in the box. Exactly what bad effects this can have depends on how color is implemented: it can range from getting the wrong colors in the rest of the document, to causing errors in the dvi-driver used to print the document.

Also of interest is the command \verb|\normalcolor|. This is normally just \verb|\relax| (i.e., does nothing) but you can use it rather like \verb|\normalfont| to set regions of the page such as captions or section headings to the ‘main document color’.

2.7 General style

\LaTeX provides many commands designed to help you produce well-structured class and package files that are both robust and portable. This section outlines some ways to make intelligent use of these.

2.7.1 Loading other files

\LaTeX provides these commands:

\begin{verbatim}
\LoadClass \LoadClassWithOptions
\RequirePackage \RequirePackageWithOptions
\end{verbatim}

for using classes or packages inside other classes or packages. We recommend strongly that you use them, rather than the primitive \verb|\input| command, for a number of reasons.

Files loaded with \verb|\input <filename>| will not be listed in the \verb|\listfiles| list. If a package is always loaded with \verb|\RequirePackage|... or \verb|\usepackage| then, even if its loading is requested several times, it will be loaded only once. By contrast, if it is loaded with \verb|\input| then it can be loaded more than once; such an extra loading may waste time and memory and it may produce strange results.
If a package provides option-processing then, again, strange results are possible if the package is \input rather than loaded by means of \usepackage or \RequirePackage ....

If the package foo.sty loads the package baz.sty by use of \input baz.sty then the user will get a warning:

\begin{verbatim}
LaTeX Warning: You have requested package `foo',
       but the package provides `baz'.
\end{verbatim}

Thus, for several reasons, using \input to load packages is not a good idea.

For example, article.sty contains just the following lines:

\begin{verbatim}
\NeedsTeXFormat{LaTeX2e}
\@obsoletefile{article.cls}{article.sty}
\LoadClass{article}
\end{verbatim}

You may wish to do the same or, if you think that it is safe to do so, you may decide to just remove myclass.sty.

\section*{2.7.2 Make it robust}

We consider it good practice, when writing packages and classes, to use \LaTeX commands as much as possible.

Thus, instead of using \def\ldots we recommend using one of \newcommand, \renewcommand or \providecommand for programming and for defining document interfaces \NewDocumentCommand, etc. (see usrguide for details of these commands).

When you define an environment, use \NewDocumentEnvironment, etc., (or \newenvironment, etc., for simple cases) instead of using \def\foo\ldots and \def\endfoo\ldots).

If you need to set or change the value of a ⟨dimen⟩ or ⟨skip⟩ register, use \setlength.

To manipulate boxes, use \LaTeX commands such as \sbox, \ hbox and \parbox rather than \setbox, \ hbox and \vbox.

Use \PackageError, \PackageWarning or \PackageInfo (or the equivalent class commands) rather than \@latexerr, \@warning or \wlog.

The advantage of this kind of practice is that your code is more readable and accessible to other experienced \LaTeX programmers.

\section*{2.7.3 Make it portable}

It is also sensible to make your files are as portable as possible. To ensure this, files must not have the same name as a file in the standard \LaTeX distribution, however similar its contents may be to one of these files. It is also still lower
risk to stick to file names which use only the ASCII range: whilst \LaTeX works natively with UTF-8, the same cannot be said with certainty for all tools. For the same reason, avoid spaces in file names.

It is also useful if local classes or packages have a common prefix, for example the University of Nowhere classes might begin with \texttt{unw}. This helps to avoid every University having its own thesis class, all called \texttt{thesis.cls}.

If you rely on some features of the \LaTeX kernel, or on a package, please specify the release-date you need. For example, the package error commands were introduced in the June 2022 release so, if you use them then you should put:

\verbatim{\needsTeXFormat{LaTeX2e}[2022-06-01]}

2.7.4 Useful hooks

It is sometimes necessary for a package to arrange for code to be executed at the start or end of the preamble, at the end of the document or at the start of every use of an environment. This can be carried out by using hooks. As a document author, you will likely be familiar with \texttt{\AtBeginDocument}, a wrapper around the more powerful command \texttt{\AddToHook}. The \TeX kernel provides a large number of dedicated hooks (applying in a pre-defined location) and generic hooks (applying to arbitrary commands): the interface for using these is described in \texttt{lthooks}. There are also hooks to apply to files, described in \texttt{lthfilehooks}.

3 The structure of a class or package

The outline of a class or package file is:

\textbf{Identification} The file says that it is a \LaTeX package or class, and gives a short description of itself.

\textbf{Preliminary declarations} Here the file declares some commands and can also load other files. Usually these commands will be just those needed for the code used in the declared options.

\textbf{Options} The file declares and processes its options.

\textbf{More declarations} This is where the file does most of its work: declaring new variables, commands and fonts; and loading other files.

3.1 Identification

The first thing a class or package file does is identify itself. Package files do this as follows:

\verbatim{\NeedsTeXFormat{LaTeX2e}\\ProvidesPackage{<package>}[<date> <other information>]}
For example:

\NeedsTeXFormat{LaTeX2e}
\ProvidesPackage{latexsym}[1998-08-17 Standard LaTeX package]

Class files do this as follows:

\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{⟨class-name⟩}[⟨date⟩ ⟨other information⟩]

For example:

\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{article}[2022-06-01 Standard LaTeX class]

The ⟨date⟩ should be given in the form ‘YYYY-MM-DD’ and must be present if the optional argument is used (this is also true for the \NeedsTeXFormat command). Any derivation from this syntax will result in low-level \TeX errors—the commands expect a valid syntax to speed up the daily usage of the package or class and make no provision for the case that the developer made a mistake!

This date is checked whenever a user specifies a date in their \documentclass or \usepackage command. For example, if you wrote:

\documentclass{article}[2022-06-01]

then users at a different location would get a warning that their copy of article was out of date.

The description of a class is displayed when the class is used. The description of a package is put into the log file. These descriptions are also displayed by the \listfiles command. The phrase Standard LaTeX must not be used in the identification banner of any file other than those in the standard \TeX distribution.

3.2 Using classes and packages

A \LaTeX package or class can load a package as follows:

\RequirePackage[⟨options⟩]{⟨package⟩}[⟨date⟩]

For example:

\RequirePackage{ifthen}[2022-06-01]

This command has the same syntax as the author command \usepackage. It allows packages or classes to use features provided by other packages. For example, by loading the ifthen package, a package writer can use the ‘if…then…else…’ commands provided by that package.

A \LaTeX class can load one other class as follows:
\LoadClass[<options>]{<class-name>}[<date>] 

For example:

\LoadClass[twocolumn]{article}

This command has the same syntax as the author command \documentclass. It allows classes to be based on the syntax and appearance of another class. For example, by loading the article class, a class writer only has to change the bits of article they don’t like, rather than writing a new class from scratch.

The following commands can be used in the common case that you want to simply load a class or package file with exactly those options that are being used by the current class.

\LoadClassWithOptions{<class-name>}[<date>]  
\RequirePackageWithOptions{<package>}[<date>]

For example:

\LoadClassWithOptions{article}[1995/12/01]  
\RequirePackageWithOptions{graphics}[1995/12/01]

### 3.3 Declaring options

Packages and classes can declare options and these can be specified by authors; for example, the twocolumn option is declared by the article class. Note that the name of an option should contain only those characters allowed in a ‘LATEX name; in particular it must not contain any control sequences.

\LaTeX supports two methods for creating options: a key–value system and a ‘simple text’ approach. The key–value system is recommended for new classes and packages, and is more flexible in handling of option classes than the simple text approach. Both option methods use the same basic structure within the \LaTeX source: declaration of options first then processing options in a second step. Both also allow options to be passed on to other packages or an underlying class. As the ‘classical’ simple text approach is conceptually more straightforward to illustrate, it is used here to show the general structure; see Section 4.4 for full details of the key–value approach.

An option is declared as follows:

\DeclareOption{<option>}{<code>}

For example, the dvips option (slightly simplified) to the graphics package is implemented as:

\DeclareOption{dvips}{\input{dvips.def}}
This means that when an author writes `\usepackage[dvips]{graphics}`, the file `dvips.def` is loaded. As another example, the `a4paper` option is declared in the `article` class to set the `\paperheight` and `\paperwidth` lengths:

\begin{verbatim}
\DeclareOption{a4paper}{%
  \setlength{\paperheight}{297mm}%
  \setlength{\paperwidth}{210mm}%
}\end{verbatim}

Sometimes a user will request an option which the class or package has not explicitly declared. By default this will produce a warning (for classes) or error (for packages); this behavior can be altered as follows:

\begin{verbatim}
\DeclareOption*{<code>}{%}
\end{verbatim}

For example, to make the package `fred` produce a warning rather than an error for unknown options, you could specify:

\begin{verbatim}
\DeclareOption*{%
  \PackageWarning{fred}{Unknown option `\CurrentOption'}%
}\end{verbatim}

Then, if an author writes `\usepackage[foo]{fred}`, they will get a warning Package `fred` Warning: Unknown option ‘foo’. As another example, the `fontenc` package tries to load a file `<ENC>enc.def` whenever the `(ENC)` option is used. This can be done by writing:

\begin{verbatim}
\DeclareOption*{%
  \input{\CurrentOption enc.def}%
}\end{verbatim}

It is possible to pass options on to another package or class, using the command `\PassOptionsToPackage` or `\PassOptionsToClass` (note that this is a specialised operation that works only for option names): see Section 4.5. For example, to pass every unknown option on to the `article` class, you can use:

\begin{verbatim}
\DeclareOption*{%
  \PassOptionsToClass{\CurrentOption}{article}%
}\end{verbatim}

If you do this then you should make sure you load the class at some later point, otherwise the options will never be processed!

So far, we have explained only how to declare options, not how to execute them. To process the options with which the file was called, you should use:

\begin{verbatim}
\ProcessOptions\relax
\end{verbatim}
This executes the \texttt{⟨code⟩} for each option that was both specified and declared (see Section 6.4 for details of how this is done).

For example, if the jane package file contains:

\begin{verbatim}
\DeclareOption{foo}{\typeout{Saw foo.}}
\DeclareOption{baz}{\typeout{Saw baz.}}
\DeclareOption*{\typeout{What’s \CurrentOption?}}
\ProcessOptions\relax
\end{verbatim}

and an author writes \texttt{\usepackage[foo,bar]{jane}}, then they will see the messages \texttt{Saw foo.} and \texttt{What’s bar}?

### 3.4 A minimal class file

Most of the work of a class or package is in defining new commands, or changing the appearance of documents. This is done in the body of the package, using commands such as \texttt{\newcommand} or \texttt{\setlength}.

There are four things that every class file must contain: these are a definition of \texttt{\normalsize}, values for \texttt{\textwidth} and \texttt{\textheight} and a specification for page-numbering. So a minimal document class file\(^1\) looks like this:

\begin{verbatim}
\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{minimal}[2022-06-01 Standard LaTeX minimal class]
\renewcommand{\normalsize}{\fontsize{10pt}{12pt}\selectfont}
\setlength{\textwidth}{6.5in}
\setlength{\textheight}{8in}
\pagenumbering{arabic} \% needed even though this class will
\hspace{2em} \% not show page numbers
\end{verbatim}

However, this class file will not support footnotes, marginals, floats, etc., nor will it provide any of the 2-letter font commands such as \texttt{\rm}; thus most classes will contain more than this minimum!

### 3.5 Example: a local letter class

A company may have its own letter class, for setting letters in the company style. This section shows a simple implementation of such a class, although a real class would need more structure.

The class begins by announcing itself as \texttt{neplet.cls}.

\begin{verbatim}
\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{neplet}[2022-06-01 NonExistent Press letter class]
\end{verbatim}

Then this next bit passes any options on to the \texttt{letter} class, which is loaded with the \texttt{a4paper} option.

\(^{1}\)This class is now in the standard distribution, as \texttt{minimal.cls}. 

11
In order to use the company letter head, it redefines the \texttt{firstpage} page style: this is the page style that is used on the first page of letters.

\begin{verbatim}
\renewcommand{\ps@firstpage}{%
  \renewcommand{\@oddhead}{<letterhead goes here>}%
  \renewcommand{\@oddfoot}{<letterfoot goes here>}%
}
\end{verbatim}

And that’s it!

### 3.6 Example: a newsletter class

A simple newsletter can be typeset with \LaTeX, using a variant of the \texttt{article} class. The class begins by announcing itself as \texttt{smplnews.cls}.

\begin{verbatim}
\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{smplnews}[2022-06-01 The Simple News newsletter class]
\newcommand{\headlinecolor}{\normalcolor}
\end{verbatim}

It passes most specified options on to the \texttt{article} class: apart from the \texttt{onecolumn} option, which is switched off, and the \texttt{green} option, which sets the headline in green.

\begin{verbatim}
\DeclareOption{onecolumn}{\OptionNotUsed}
\DeclareOption{green}{\renewcommand{\headlinecolor}{\color{green}}}
\DeclareOption*{\PassOptionsToClass{\CurrentOption}{article}}
\ProcessOptions\relax
\end{verbatim}

It then loads the class \texttt{article} with the option \texttt{twocolumn}.

\begin{verbatim}
\LoadClass[twocolumn]{article}
\end{verbatim}

Since the newsletter is to be printed in colour, it now loads the \texttt{color} package. The class does not specify a device driver option since this should be specified by the user of the \texttt{smplnews} class.

\begin{verbatim}
\RequirePackage{color}
\end{verbatim}

The class then redefines \texttt{\maketitle} to produce the title in \texttt{72 pt} Helvetica bold oblique, in the appropriate colour.
\renewcommand{\maketitle}{%
\twocolumn[%
  \fontsize{72}{80}\fontfamily{phv}\fontseries{b}\%
  \fontshape{sl}\selectfont\headlinecolor
  \@title
 ]%
}

It redefines \section and switches off section numbering.

\renewcommand{\section}{%
  \@startsection
  \{section\}{1}{0pt}{-1.5ex plus -1ex minus -.2ex}%
  \{1ex plus .2ex\}{\large\sffamily\slshape\headlinecolor}%
}

\setcounter{secnumdepth}{0}

It also sets the three essential things.

\renewcommand{\normalsize}{\fontsize{9}{10}\selectfont}
\setlength{\textwidth}{17.5cm}
\setlength{\textheight}{25cm}

In practice, a class would need more than this: it would provide commands for issue numbers, authors of articles, page styles and so on; but this skeleton gives a start. The \texttt{ltnews} class file is not much more complex than this one.

4 Commands for class and package writers

This section describes briefly each of the commands for class and package writers. To find out about other aspects of the system, you should also read \textit{\LaTeX}: A Document Preparation System, \textit{The \LaTeX\ Companion} and \textit{\LaTeX\ \texttt{2e} for Authors}.

4.1 Identification

The first group of commands discussed here are those used to identify your class or package file.

\texttt{\NeedsTeXFormat{⟨format-name⟩} [⟨release-date⟩]}

This command tells \TeX\ that this file should be processed using a format with name \texttt{⟨format-name⟩}. You can use the optional argument \texttt{⟨release-date⟩} to further specify the earliest release date of the format that is needed. When the release date of the format is older than the one specified a warning will be generated. The standard \texttt{⟨format-name⟩} is \texttt{LaTeX2e}. The date, if present, must be in the form YYYY-MM-DD.

Example:
People often don’t know what date to put here. For the kernel, you can find out the right one by consulting changes.txt and select the release date of a new feature you are interested in. This is slightly different for packages as they are released throughout the year: you will need to consult their change history.

This declares that the current file contains the definitions for the document class ⟨class-name⟩ or package ⟨package-name⟩.

The optional ⟨release-info⟩, if used, must contain:

- the release date of this version of the file, in the form YYYY-MM-DD;
- optionally followed by a space and a short description, possibly including a version number.

The above syntax must be followed exactly so that this information can be used by \LoadClass or \documentclass (for classes) or \RequirePackage or \usepackage (for packages) to test that the release is not too old.

The whole of this ⟨release-info⟩ information is displayed by \listfiles and should therefore not be too long.

Example:

\ProvidesClass{article}[2022-06-01 v1.0 Standard LaTeX class]
\ProvidesPackage{ifthen}[2022-06-01 v1.0 Standard LaTeX package]

This is similar to the two previous commands except that here the full filename, including the extension, must be given. It is used for declaring any files other than main class and package files.

Example:

\ProvidesFile{T1enc.def}[2022-06-01 v1.0 Standard LaTeX file]

Note that the phrase \texttt{Standard LaTeX must not} be used in the identification banner of any file other than those in the standard \texttt{LATEX} distribution.

4.2 Loading files

This group of commands can be used to create your own document class or package by building on existing classes or packages.
Packages and classes should use these commands to load other packages.

The use of \RequirePackage is the same as the author command \usepackage. Examples:

\RequirePackage{ifthen}[2022-06-01]
\RequirePackageWithOptions{graphics}[2022-06-01]

\LoadClass \LoadClassWithOptions

These commands are for use only in class files, they cannot be used in packages files; they can be used at most once within a class file.

The use of \LoadClass is the same as the use of \documentclass to load a class file.

Examples:

\LoadClass{article}[2022-06-01]
\LoadClassWithOptions{article}[2022-06-01]

The two WithOptions versions simply load the class (or package) file with exactly those options that are being used by the current file (class or package). See below, in 4.5, for further discussion of their use.

4.3 Delaying code

As noted earlier, a sophisticated hook system is available and described in lthooks. Here, we document a small set of convenient short names for common hooks.

These first two commands are also intended primarily for use within the \⟨code⟩ argument of \DeclareOption or \DeclareOption*.

\AtEndOfClass \AtEndOfPackage

These commands declare \langle code\rangle that is saved away internally and then executed after processing the whole of the current class or package file.

Repeated use of these commands is permitted: the code in the arguments is stored (and later executed) in the order of their declarations.

\AtBeginDocument \AtEndDocument

These commands declare \langle code\rangle to be saved internally and executed while \LaTeX is executing \begin{document} or \end{document}.
The \texttt{code} specified in the argument to \texttt{AtBeginDocument} is executed near the end of the \texttt{\begin{document}} code, \textit{after} the font selection tables have been set up. It is therefore a useful place to put code which needs to be executed after everything has been prepared for typesetting and when the normal font for the document is the current font.

The \texttt{AtBeginDocument} hook should not be used for code that does any typesetting since the typeset result would be unpredictable.

The \texttt{code} specified in the argument to \texttt{AtEndDocument} is executed at the beginning of the \texttt{\end{document}} code, \textit{before} the final page is finished and before any leftover floating environments are processed. If some of the \texttt{code} is to be executed after these two processes, you should include a \texttt{\clearpage} at the appropriate point in \texttt{code}.

Repeated use of these commands is permitted: the code in the arguments is stored (and later executed) in the order of their declarations.

\subsection{Creating and using keyval options}

As with any key–value input, using key–value pairs as package or class options has two parts: creating the key options and setting (using) them. Options created in this way \textit{may} be used after package loading as general key–value settings: this will depend on the nature of the underlying code.

\begin{verbatim}
\DeclareKeys \[\texttt{\family}\] \{(declarations)\}
\end{verbatim}

This command creates a series of options from a comma-separated \texttt{(declarations)} list. Each entry in this list is a key–value pair, with the \texttt{key} having one or more \texttt{properties}. A small number of ‘basic’ \texttt{properties} are described below. The full range of properties, provided by \texttt{l3keys}, can also be used for more powerful processing. See \texttt{interface3} for the full details.

The basic properties provided here are

\begin{itemize}
\item \texttt{.code} — execute arbitrary code
\item \texttt{.if} — sets a \LaTeX \texttt{if...} switch
\item \texttt{.ifnot} — sets an inverted \LaTeX \texttt{if...} switch
\item \texttt{.store} — stores a value in a macro
\item \texttt{.usage} — defines whether the option can be given only when loading (\texttt{load}), in the preamble (\texttt{preamble}) or has no limitation on scope (\texttt{general})
\end{itemize}

The part of the \texttt{key} before the \texttt{property} is the \texttt{name}, with the \texttt{value} working with the \texttt{property} to define the behavior of the option.

For example, with
three options would be created. The option `draft` can be given anywhere in the preamble, and will set a switch called `\if@mypkg@draft`. The option `name` can only be given during package loading, and will save whatever value it is given in `\@mypkg@name`. Finally, the option `second-name` can be given anywhere, and will save its value in `\@mypkg@other@name`.

Keys created *before* the use of `\ProcessKeyOptions` act as package options.

\DeclareUnknownKeyHandler{⟨family⟩}{⟨code⟩}

The command `\DeclareUnknownKeyHandler` may be used to define the behavior when an undefined key is encountered. The ⟨code⟩ will receive the unknown key name as #1 and the value as #2. These can then be processed as appropriate, e.g. by forwarding to another package. The entire option is available as `\CurrentOption`, should it be necessary to pass on options which may or may not contain an = sign. For example, this may be used to pass an unknown option on to a non-keyval class such as `article`:

\DeclareUnknownKeyHandler{%  \PassOptionsToClass{\CurrentOption}{article} }

\ProcessKeyOptions{⟨family⟩}

The `\ProcessKeyOptions` function is used to check the current option list against the keys defined for ⟨family⟩. Global (class) options and local (package) options are checked when this function is called in a package. The command will process all options given the current package or class: there is no need to also apply `\ProcessOptions`.

\SetKeys{⟨family⟩}{⟨keyvals⟩}

Sets (applies) the explicit list of ⟨keyvals⟩ for the ⟨family⟩: if the latter is not given, the value of `\@curname` is used. This command may be used within a package to set options before or after using `\ProcessKeyOptions`.

### 4.5 Passing options around

These two commands are also very useful within the ⟨code⟩ argument of options.
The command \PassOptionsToPackage takes the 
\\{options-list\} to \package\{package-name\}. This means that it adds the 
\{option-list\} to the list of options used by any future \RequirePackage or \usepackage command for
\package\{package-name\}.

Example:

\PassOptionsToPackage{foo,bar}{fred}
\RequirePackage[baz]{fred}

is the same as:

\RequirePackage[foo,bar,baz]{fred}

Similarly, \PassOptionsToClass may be used in a class file to pass options to
another class to be loaded with \LoadClass.

The effects and use of these two commands should be contrasted with those of
the following two (documented above, in 4.2):

\LoadClassWithOptions
\RequirePackageWithOptions

The command \RequirePackageWithOptions is similar to \RequirePackage, but it always loads the required package with exactly the same option list as that being used by the current class or package, rather than with any option
explicitly supplied or passed on by \PassOptionsToPackage.

The main purpose of \LoadClassWithOptions is to allow one class to simply
build on another, for example:

\LoadClassWithOptions{article}

This should be compared with the slightly different construction

\DeclareOption*{(\PassOptionsToClass{\CurrentOption}{article})}
\ProcessOptions\relax
\LoadClass{article}

As used above, the effects are more or less the same, but the first is a lot less
to type; also the \LoadClassWithOptions method runs slightly quicker.

If, however, the class declares options of its own then the two constructions are
different. Compare, for example:

\DeclareOption{landscape}{\@landscape=true}
\ProcessOptions\relax
\LoadClassWithOptions{article}
with:

\DeclareOption{landscape}{\@landscapetrue}
\DeclareOption*{\PassOptionsToClass{\CurrentOption}{article}}
\ProcessOptions\relax
\LoadClass{article}

In the first example, the \texttt{article} class will be loaded with option \texttt{landscape} precisely when the current class is called with this option. By contrast, in the second example it will never be called with option \texttt{landscape} as in that case \texttt{article} is passed options only by the default option handler, but this handler is not used for \texttt{landscape} because that option is explicitly declared.

4.6 Safe file commands

These commands deal with file input; they ensure that the non-existence of a requested file can be handled in a user-friendly way.

\begin{verbatim}
\IfFileExists {{\textit{file-name}}} {{\textit{true}}} {{\textit{false}}}
\end{verbatim}

If the file exists then the code specified in \texttt{\langle true\rangle} is executed.
If the file does not exist then the code specified in \texttt{\langle false\rangle} is executed.
This command does \textit{not} input the file.

\begin{verbatim}
\InputIfFileExists {{\textit{file-name}}} {{\textit{true}}} {{\textit{false}}}
\end{verbatim}

This inputs the file \texttt{\langle file-name\rangle} if it exists and, immediately before the input, the code specified in \texttt{\langle true\rangle} is executed.
If the file does not exist then the code specified in \texttt{\langle false\rangle} is executed.
It is implemented using \texttt{\IfFileExists}.

4.7 Reporting errors, etc

These commands should be used by third party classes and packages to report errors, or to provide information to authors.

\begin{verbatim}
\ClassError {{\textit{class-name}}} {{\textit{error-text}}} {{\textit{help-text}}}
\PackageError {{\textit{package-name}}} {{\textit{error-text}}} {{\textit{help-text}}}
\end{verbatim}

These produce an error message. The \texttt{\langle error-text\rangle} is displayed and the \texttt{?} error prompt is shown. If the user types \texttt{h}, they will be shown the \texttt{\langle help-text\rangle}.

Within the \texttt{\langle error-text\rangle} and \texttt{\langle help-text\rangle}: \texttt{\protect} can be used to stop a command from expanding; \texttt{\MessageBreak} causes a line-break; and \texttt{\space} prints a space.
Note that the \langle error-text\rangle will have a full stop added to it, so do not put one into the argument.

For example:

\newcommand{\foo}{FOO}
\PackageError{ethel}{%
  Your hovercraft is full of eels, \MessageBreak
  and \protect\foo\space is \foo
}{}
  Oh dear! Something’s gone wrong, \MessageBreak
  \space \space Try typing \space \textless return\textgreater
  \space to proceed, ignoring \protect\foo.
}

produces this display:

! Package ethel Error: Your hovercraft is full of eels, (ethel) and \foo is FOO.

See the ethel package documentation for explanation.

If the user types h, this will be shown:

Oh dear! Something’s gone wrong.
Try typing \textless return\textgreater to proceed, ignoring \foo.

The four Warning commands are similar to the error commands, except that they produce only a warning on the screen, with no error prompt.

The first two, Warning versions, also show the line number where the warning occurred, whilst the second two, WarningNoLine versions, do not.

The two Info commands are similar except that they log the information only in the transcript file, including the line number. There are no NoLine versions of these two.

Within the \langle warning-text\rangle and \langle info-text\rangle: \protect can be used to stop a command from expanding; \MessageBreak causes a line-break; and \space prints a space. Also, these should not end with a full stop as one is automatically added.
5 Miscellaneous commands, etc.

5.1 Layout parameters

`\paperheight`

`\paperwidth`

These two parameters are usually set by the class to be the size of the paper being used. This should be actual paper size, unlike `\textwidth` and `\textheight` which are the size of the main text body within the margins.

5.2 Case changing

`\MakeUppercase {\langle text\rangle}`

`\MakeLowercase {\langle text\rangle}`

`\MakeTitlecase {\langle text\rangle}`

As described in `usrguide`, case changing for text should be carried out using the commands `\MakeUppercase`, `\MakeLowercase` and `\MakeTitlecase`. If you need to change the case of programmatic material, the team strongly suggest using the L3 programming layer commands in the `str` module. If you do not wish to do this, you should use the `\TeX \uppercase` and `\lowercase` primitives in this situation only.

5.3 Better user-defined math display environments

`\ignorespacesafterend`

Suppose that you want to define an environment for displaying text that is numbered as an equation. A straightforward way to do this is as follows:

\newenvironment{texteqn}{% 
  \begin{equation} 
  \begin{minipage}{0.9\linewidth} 
  }{% 
  \end{minipage} 
  \end{equation} 
 }

However, if you have tried this then you will probably have noticed that it does not work perfectly when used in the middle of a paragraph because an inter-word space appears at the beginning of the first line after the environment.

You can avoid this problem using `\ignorespacesafterend`; it should be inserted as shown here:

\ignorespacesafterend
5.4 Normalising spacing

This command should be used to restore the normal settings of the parameters that affect spacing between words, sentences, etc.

An important use of this feature is to correct a problem, reported by Donald Arseneau, that punctuation in page headers has always (in all known TeX formats) been potentially wrong whenever a page break happens while a local setting of the space codes is in effect. These space codes are changed by, for example, the command \frenchspacing and the verbatim environment.

It is normally given the correct definition automatically in \begin{document} and so need not be explicitly set; however, if it is explicitly made non-empty in a class file then automatic default setting will be over-ridden.

5.5 Querying localisation

Localisation information is needed to customise a range of outputs. The \TeX kernel does not itself manage localisation, which is well-served by the bundles babel and polyglossia. To allow the kernel and other packages to access the current localisation information provided by babel or polyglossia, the command \BCPdata is defined by the kernel. The initial kernel definition expands to tag parts for en-US, as the kernel does not track localisation but does start out with a broadly US English setup. However, if babel or polyglossia are loaded, it is redefined expand to the BCP-47 information from the appropriate package. The supported arguments are the BCP-47 tag breakdowns:

- tag The full BCP-47 tag (e.g. en-US)
- language (e.g., de)
- region (e.g., AT)
- script (e.g., Latn)
- variant (e.g., 1901)
- extension.t (transformation, e.g., en-t-ja)
• extension.u (additional locale information, e.g., ar-u-nu-latn)
• extension.x (private use area, e.g., la-x-classic)

The information for the main language for a document is be provided if these are prefixed by main, e.g. main.language will expand to the main language even if another language is currently active.

In addition to the tag breakdown, the following semantic arguments are supported

• casing The tag for case changing, e.g. el-x-iota could be selected rather than el to select a capital adscript iota on uppercasing an ypogegrammeni

For example, the case changing command \MakeUppercase is (conceptually) defined as

\ExpandArgs{e}\MakeUppercaseAux{\BCPdata{casing}}{#1}

where #1 is the user input and the first argument to \MakeUppercaseAux takes two arguments, the locale and input text.

5.6 Extended and expandable references of properties

A property is something that \LaTeX can track while processing the document, such as a page number, a heading number, other counter values, a heading title, a position on the page, etc. The current value of such properties can be labeled and written to the aux-file. It can then be referenced in the next compilation, similar to the way the standard \label/\ref commands work (they record/reference a fixed set of properties: label, page, title, and target).

\RecordProperties{⟨label⟩}{⟨list of properties⟩}

This command writes the value(s) of the ⟨list of properties⟩ aux-file labeled by ⟨label⟩. Recorded are either the values current when \RecordProperties is called or the value current when the next shipout happens—which depends on the declaration for each property. The arguments ⟨label⟩ and ⟨list of properties⟩ can contain commands that are expanded. ⟨label⟩ can expand to an arbitrary string (as long as it can safely be written to the aux-file) but note that the label names of \label and \RecordProperties share a singe namespace. This means that you get a Label ‘A’ multiply defined warning with the following code:

\label{A}\RecordProperties{A}{abspage}

\RefProperty{⟨label⟩}{⟨property⟩}

This command allows to reference the value of the property ⟨property⟩ recorded in the previous run and labeled by ⟨label⟩. Differently to the standard \ref
command the command is expandable and the value can for example—if it is a number—be used in an assignment.\footnote{For this to work the default value for the property would need to be a number too, because recorded values aren’t known in the first \LaTeX run.}

\begin{verbatim}
\section{A section}
\RecordProperties{mylabel}{pagenum,counter}
\RefProperty{mylabel}{counter} \% outputs section
\setcounter{mycounter}{\RefProperty{mylabel}{pagenum}}
\end{verbatim}

As \texttt{\RefProperty} is expandable it can not issue a rerun warning if a label is not found. If needed such a warning can be forced by the following command:

\begin{verbatim}
\RefUndefinedWarn{{\langle label\rangle}}{{\langle property\rangle}}
\end{verbatim}

\LaTeX predefines a set of properties, this set contains also the properties stored by the standard \texttt{\label} command. In the list below “default” indicates the value returned when the value is not yet known (i.e., if it wasn’t recorded in the previous run and “at shipout” means that this property is not recorded immediately when \texttt{\RecordProperties} is used but during the next \texttt{\shipout}.

\begin{description}
\item[abspage (default: 0, at shipout)] The absolute value of the current page: starts at 1 and increases monotonically at each shipout.
\item[page (default: 0, at shipout)] The current page as given by \texttt{\thepage}: this may or may not be a numerical value, depending on the current style. Contrast with \texttt{abspage}. You get this value also with the standard \texttt{\label}/\texttt{\pageref}.
\item[pagenum (default: 0, at shipout)] The current page as arabic number. This is suitable for integer operations and comparisions.
\item[label (default: ??)] The content of \texttt{\@currentlabel}. This is the value that you get also with the standard \texttt{\label}/\texttt{\ref}.
\item[title (default: \textbf{??})] The content of \texttt{\@currentlabelname}. This command is filled beside others by the nameref package and some classes (e.g. memoir) and typically gives the title defined in the document by some sectioning command.
\item[target (default: \texttt{(empty)})] The content of \texttt{\@currentHref}. This command contains the name of the last destination it created.
\item[pagetarget (default: \texttt{(empty)}, at shipout)] The content of \texttt{\@currentHpage}. This command is filled by hyperref (version v7.01c or newer) and holds the name of the last page anchor it created.
\item[counter (default: \texttt{(empty)})] The content of \texttt{\@currentcounter}. This command contains after a \texttt{\refstepcounter} the name of the counter.
\end{description}
These properties records the \textit{x} and \textit{y} coordinates of a point previously stored with \texttt{pdfsavepos} or savepos.

E.g. (if bidi is used it can be necessary to save the position before and after the label):

\begin{verbatim}
\pdfsavepos
\RecordProperties{myposition}{xpos,ypos}
\pdfsavepos
\end{verbatim}

Class and package authors can define more properties to store other values they are interested in.

\begin{verbatim}
\NewProperty\{langle name\rangle\}\{langle setpoint\rangle\}\{default\}\{langle code\rangle\}
\SetProperty\{langle name\rangle\}\{langle setpoint\rangle\}\{default\}\{langle code\rangle\}
\end{verbatim}

These commands declare or change a property \textit{\textlangle name\rangle\textrangle}. If a new property is declared within a package it is suggested that its name is always structured as follows: \textit{\textlangle package-name\rangle/\textlangle property-name\rangle}. \textit{\textlangle setpoint\rangle} is either \textit{now} or \textit{shipout} and decides if the value is written directly or at the next shipout. \textit{\textlangle default\rangle} is used if the property is referenced but not yet known, e.g., in the first run. \textit{\textlangle code\rangle} is the code executed when storing the value. For example, the \textit{pagenum} property is declared as

\begin{verbatim}
\NewProperty\{pagenum\}\{shipout\}\{0\}\{the\\value{page}\}
\end{verbatim}

The commands related to properties are offered as a set of CamelCase commands for traditional \LaTeX\ packages (and for use in the document preamble if needed) as well as \texttt{expl3} commands for modern packages, that use the L3 programming layer of \LaTeX. The \texttt{expl3} commands and more details can be found in \texttt{ltproperties-doc.pdf}.

### 5.7 Preparing link targets

Active links in a document need targets to which they can jump to. Such targets are often created automatically (if the package \texttt{hyperref} is loaded) by the \texttt{refstepcounter} command but there are also cases where class or package authors need to add a target manually, for example, in unnumbered sectioning commands or in environments. For this \LaTeX\ provides the following commands.

\textit{Without hyperref} they do nothing or insert only a \texttt{whatsits} (to ensure that spacing doesn’t change when hyperref is loaded), \textit{with hyperref} they add the necessary targets. Details about the behavior and the arguments of the following commands can be found in \texttt{hyperref-linktarget.pdf}.

\footnote{Only change properties that you have declared. The declarations of standard properties of \LaTeX\ and properties of other packages should never be altered!}
This command prepares the creations of targets.

These commands allow to enable and disable locally the creation of targets. This can be useful to suppress targets otherwise created automatically by \refstepcounter.

This changes the name of the next target that will be created.

6 Commands superseded for new material

A small number of commands were introduced as part of \LaTeX{} 2e in the mid-1990s, are widely used but have been superseded by more modern methods. These are covered here as they are likely to be encountered routinely in existing classes and packages.

6.1 Defining commands

The *-forms of these commands should be used to define commands that are not, in \TeX{} terms, long. This can be useful for error-trapping with commands whose arguments are not intended to contain whole paragraphs of text.

This command takes the same arguments as \newcommand but it declares a robust command, even if some code within the (definition) is fragile. You can use this command to define new robust commands, or to redefine existing commands and make them robust. A log is put into the transcript file if a command is redefined.

For example, if \texttt{\seq} is defined as follows:

\begin{verbatim}
\\DeclareRobustCommand{\seq}[2][n]{% 
  \ifmmode 
    #1_{1}\ldots#1_{#2}% 
  \else 
    \PackageWarning{fred}{You can't use \protect\seq\space in text}% 
  \fi
}
\end{verbatim}
Then the command \seq can be used in moving arguments, even though \ifmmode cannot, for example:

\section{Stuff about sequences $\seq{x}$}

Note also that there is no need to put a \texttt{relax} before the \texttt{ifmmode} at the beginning of the definition; this is because the protection given by this \texttt{relax} against expansion at the wrong time will be provided internally.

\CheckCommand {⟨cmd⟩} {⟨num⟩} {⟨default⟩} {⟨definition⟩}
\CheckCommand* {⟨cmd⟩} {⟨num⟩} {⟨default⟩} {⟨definition⟩}

This takes the same arguments as \texttt{newcommand} but, rather than define ⟨cmd⟩, it just checks that the current definition of ⟨cmd⟩ is exactly as given by ⟨definition⟩. An error is raised if these definitions differ.

This command is useful for checking the state of the system before your package starts altering the definitions of commands. It allows you to check, in particular, that no other package has redefined the same command.

### 6.2 Option declaration

The following commands deal with the declaration and handling of options to document classes and packages using a classical ‘simple text’ approach. Every option name must be a ‘\LaTeX name’.

There are some commands designed especially for use within the ⟨code⟩ argument of these commands (see below).

\DeclareOption {⟨option-name⟩} {⟨code⟩}

This makes ⟨option-name⟩ a ‘declared option’ of the class or package in which it is put.

The ⟨code⟩ argument contains the code to be executed if that option is specified for the class or package; it can contain any valid \LaTeX construct.

Example:

\DeclareOption{twoside}{\@twosidetrue}

\DeclareOption* {⟨code⟩}

This declares the ⟨code⟩ to be executed for every option which is specified for, but otherwise not explicitly declared by, the class or package; this code is called the ‘default option code’ and it can contain any valid \LaTeX construct.

If a class file contains no \DeclareOption* then, by default, all specified but undeclared options for that class will be silently passed to all packages (as will the specified and declared options for that class).

If a package file contains no \DeclareOption* then, by default, each specified but undeclared option for that package will produce an error.
6.3 Commands within option code

These two commands can be used only within the \textit{code} argument of either \texttt{\textbackslash DeclareOption} or \texttt{\textbackslash DeclareOption*}. Other commands commonly used within these arguments can be found in the next few subsections.

\texttt{\textbackslash CurrentOption}

This expands to the name of the current option.

\texttt{\textbackslash OptionNotUsed}

This causes the current option to be added to the list of ‘unused options’.

6.4 Option processing

\texttt{\textbackslash ProcessOptions}

This command executes the \textit{code} for each selected option.

We shall first describe how \texttt{\textbackslash ProcessOptions} works in a package file, and then how this differs in a class file.

To understand in detail what \texttt{\textbackslash ProcessOptions} does in a package file, you have to know the difference between \textit{local} and \textit{global} options.

- **Local options** are those which have been explicitly specified for this particular package in the \textit{options} argument of any of these:

  \begin{footnotesize}
  \begin{itemize}
  \item \texttt{\textbackslash PassOptionsToPackage[\textit{options}] \usepackage[\textit{options}]}
  \item \texttt{\textbackslash RequirePackage[\textit{options}]}
  \end{itemize}
  \end{footnotesize}

- **Global options** are any other options that are specified by the author in the \textit{options} argument of \texttt{\textbackslash documentclass[\textit{options}]}.

For example, suppose that a document begins:

\begin{footnotesize}
\begin{verbatim}
\documentclass[german,twocolumn]{article}
\usepackage{gerhardt}
\end{verbatim}
\end{footnotesize}

whilst package \texttt{gerhardt} calls package \texttt{fred} with:

\begin{footnotesize}
\begin{verbatim}
\PassOptionsToPackage{german,dvips,a4paper}{fred}
\RequirePackage{errorshow}{fred}
\end{verbatim}
\end{footnotesize}

then:

- \texttt{fred’s} local options are \texttt{german}, \texttt{dvips}, \texttt{a4paper} and \texttt{errorshow};
• fred’s only global option is twocolumn.

When \ProcessOptions is called, the following happen.

• First, for each option so far declared in fred.sty by \DeclareOption, it looks to see if that option is either a global or a local option for fred: if it is then the corresponding code is executed. This is done in the order in which these options were declared in fred.sty.

• Then, for each remaining local option, the command \ds@<option> is executed if it has been defined somewhere (other than by a \DeclareOption); otherwise, the ‘default option code’ is executed. If no default option code has been declared then an error message is produced. This is done in the order in which these options were specified.

Throughout this process, the system ensures that the code declared for an option is executed at most once.

Returning to the example, if fred.sty contains:

\DeclareOption{dvips}{\typeout{DVIPS}}
\DeclareOption{german}{\typeout{GERMAN}}
\DeclareOption{french}{\typeout{FRENCH}}
\DeclareOption*{\PackageWarning{fred}{Unknown ‘\CurrentOption’}}
\ProcessOptions\relax

then the result of processing this document will be:

DVIPS
GERMAN
Package fred Warning: Unknown ‘a4paper’.
Package fred Warning: Unknown ‘errorshow’.

Note the following:

• the code for the dvips option is executed before that for the german option, because that is the order in which they are declared in fred.sty;

• the code for the german option is executed only once, when the declared options are being processed;

• the a4paper and errorshow options produce the warning from the code declared by \DeclareOption* (in the order in which they were specified), whilst the twocolumn option does not: this is because twocolumn is a global option.

In a class file, \ProcessOptions works in the same way, except that: all options are local; and the default value for \DeclareOption* is \OptionNotUsed rather than an error.
Note that, because `\ProcessOptions` has a `*`-form, it is wise to follow the non-star form with `\relax`, as in the previous examples, since this prevents unnecessary look ahead and possibly misleading error messages being issued.

`\ProcessOptions*`

This is like `\ProcessOptions` but it executes the options in the order specified in the calling commands, rather than in the order of declaration in the class or package. For a package this means that the global options are processed first.

`\ExecuteOptions \{⟨options-list⟩\}`

It can be used to provide a ‘default option list’ just before `\ProcessOptions`. For example, suppose that in a class file you want to set up the default design to be: two-sided printing; 11pt fonts; in two columns. Then it could specify:

```latex
\ExecuteOptions{11pt,twoside,twocolumn}
```
