The pyluatex package

Tobias Enderle
https://github.com/tndrle/PyLuaTeX

v0.3.0 (2021/08/07)

Execute Python code on the fly in your \LaTeX documents

PyLuaTeX allows you to execute Python code and to include the resulting output in your \LaTeX documents in a single compilation run. \LaTeX documents must be compiled with Lua\LaTeX for this to work.

1 Example

1. \LaTeX document example.tex

   Note: PyLuaTeX starts Python 3 using the command \texttt{python3} by default. If \texttt{python3} does not start Python 3 on your system, find the correct command and replace \texttt{\usepackage[pyluatex]{pyluatex}} with \texttt{\usepackage[executable={your python command}]{pyluatex}}. For example, \texttt{\usepackage[executable=python.exe]{pyluatex}}.

\begin{verbatim}
\documentclass{article}
\usepackage{pyluatex}
\begin{python}
import math
import random
random.seed(0)
greeting = 'Hello PyLuaTeX!'\n\end{python}

\newcommand{\randint}[2]{\py{random.randint(#1, #2)}}
\begin{document}
\py{greeting}
$\sqrt{371} = \py{math.sqrt(371)}$
\randint{2}{5}
\end{document}
\end{verbatim}
2. Compile using \LaTeX{} (shell escape is required)

\begin{verbatim}
lualatex -shell-escape example.tex
\end{verbatim}

**Note:** Running \LaTeX{} with the shell escape option enabled allows arbitrary code to be executed. For this reason, it is recommended to compile trusted documents only.

### 1.1 Further Examples

The folder `example` contains additional example documents:

- `readme-example.tex`
  The example above
- `sessions.tex`
  Demonstrates the use of different Python sessions in a document
- `data-visualization.tex`
  Demonstrates the visualization of data using `pgfplots` and `pandas`
- `matplotlib-external.tex`
  Demonstrates how `matplotlib` plots can be generated and included in a document
- `matplotlib-pgf.tex`
  Demonstrates how `matplotlib` plots can be generated and included in a document using `PGF`
- `typesetting-example.tex`
  The code typesetting example below
- `typesetting-listings.tex`
  A detailed example for typesetting code and output with the `listings` package
- `typesetting-minted.tex`
  A detailed example for typesetting code and output with the `minted` package

For more intricate use cases have a look at our tests in the folder `test`.

### 2 Installation

PyLuaTeX is available in TeX Live, MiKTeX, and on CTAN\(^1\) as `pyluatex`.

To install PyLuaTeX in **TeX Live** run `tlmgr install pyluatex`.

In **MiKTeX**, PyLuaTeX can be installed in the **MiKTeX Console**.

To install PyLuaTeX **manually**, do the following steps:

1. Locate your local `TEXMF` folder
   The location of this folder may vary. Typical defaults for TeX Live are `~/texmf` for Linux, `~/Library/texmf` for macOS, and `C:\Users\<user name>\texmf` for Windows. If you are lucky,

\(^1\)https://ctan.org/pkg/pyluatex
the command `kpsewhich -var-value=TEXMFHOME` tells you the location. For MiKTeX, the folder can be found and configured in the *MiKTeX Console*.

2. Download the latest release\(^2\) of PyLuatex

3. Put the downloaded files in the folder `TEXMF/tex/latex/pyluatex` (where `TEXMF` is the folder located in 1.)

   The final folder structure must be
   
   ```plaintext
   TEXMF/tex/latex/pyluatex/
   |-- pyluatex-interpreter.py
   |-- pyluatex.json.lua
   |-- pyluatex.lua
   |-- pyluatex.sty
   |-- ...
   ```

3 Reference

PyLuatex offers a simple set of options, macros and environments.

Most macros and environments are available as *quiet* versions as well. They have the suffix `q` in their name, e.g. \texttt{\textbackslash pycq} or \texttt{\textbackslash pyfileq}. The quiet versions suppress any output, even if the Python code explicitly calls `print()`. This is helpful if you want to process code or output further and do your own typesetting. For an example, see the Typesetting Code section.

3.1 Package Options

- \texttt{\textbackslash usepackage}[verbose]{pyluatex}

  If this option is enabled, Python input and output is written to the log file.

  \textit{Example:} \texttt{\textbackslash usepackage}[verbose]{pyluatex}

- \texttt{\textbackslash usepackage}[executable=/usr/local/bin/python3]{pyluatex}

  Specifies the path to the Python executable. (default: \texttt{python3})

  \textit{Example:} \texttt{\textbackslash usepackage}[executable=/usr/local/bin/python3]{pyluatex}

3.2 Macros

- \texttt{\textbackslash py(code)}

  Executes (object-like) \texttt{code} and writes its string representation to the document.

  \textit{Example:} \texttt{\textbackslash py(3 + 7)}

- \texttt{\textbackslash pyq(code)}

  Executes (object-like) \texttt{code}. Any output is suppressed.

  \textit{Example:} \texttt{\textbackslash pyq(3 + 7)}

\(^2\)https://github.com/tndrie/PyLuatex/releases/latest
• \pyc{code}
  Executes code. Output (e.g. from a call to print()) is written to the document.
  *Examples:* \pyc{x = 5}, \pyc{print(’hello’)}

• \pycq{code}
  Executes code. Any output is suppressed.
  *Example:* \pycq{x = 5}

• \pyfile{path}
  Executes the Python file specified by path. Output (e.g. from a call to print()) is written to the document.
  *Example:* \pyfile{main.py}

• \pyfileq{path}
  Executes the Python file specified by path. Any output is suppressed.
  *Example:* \pyfileq{main.py}

• \pysession{session}
  Selects session as Python session for subsequent Python code.
  The session that is active at the beginning is default.
  *Example:* \pysession{main}

### 3.3 Environments

• \texttt{python}
  Executes the provided block of Python code.
  The environment handles characters like _, #, $, \\, etc.
  Code on the same line as \texttt{\begin{python}} is ignored, i.e., code must start on the next line.
  If leading spaces are present they are gobbled automatically up to the first level of indentation.
  *Example:*

  \begin{python}
  x = ’Hello PyLaTeX’
  print(x)
  \end{python}

• \texttt{pythonq}
  Same as the \texttt{python} environment, but any output is suppressed.
  You can create your own environments based on the \texttt{python} and \texttt{pythonq} environments. However, since they are verbatim environments, you have to use the macro \texttt{PyLTVerbatimEnv} in your environment definition, e.g.

  \newenvironment{custompy}{\PyLTVerbatimEnv\begin{python}}
4 Requirements

- Lua\TeX
- Python 3
- Linux, macOS or Windows

5 Typesetting Code

Sometimes, in addition to having Python code executed and the output written to your document, you also want to show the code itself in your document. PyLuaTeX does not offer any macros or environments that directly typeset code. However, PyLuaTeX has a code and output buffer which you can use to create your own typesetting functionality. This provides a lot of flexibility for your typesetting.

After a PyLuaTeX macro or environment has been executed, the corresponding Python code and output can be accessed via the Lua functions `pyluatex.get_last_code()` and `pyluatex.get_last_output()`, respectively. Both functions return a Lua table\(^3\) (basically an array) where each table item corresponds to a line of code or output.

A simple example for typesetting code and output using the `listings` package would be:

\begin{luacode}
function pytypeset()
  tex.print("\begin{lstlisting}[language=Python]"
  tex.print(pyluatex.get_last_code())
  tex.print("\end{lstlisting}")
  tex.print("\") -- ensure newline
end
\end{luacode}

\newcommand*{\pytypeset}{%
 \noindent \textbf{Input:}\
 \directlua{pytypeset()}
 \textbf{Output:}}

\footnote{\url{https://www.lua.org/pil/2.5.html}}
Notice that we use the \texttt{pythonq} environment, which suppresses any output. After that, the custom macro \texttt{pytypeset} is responsible for typesetting the code and its output.

Using a different code listings package like \texttt{minted}, or typesetting inline code is very easy. You can also define your own environments that combine Python code and typesetting. See the \texttt{typesetting-*.tex} examples in the \texttt{example} folder.

6 How It Works

PyLuaTeX runs a Python \texttt{InteractiveInterpreter} (actually several if you use different sessions) in the background for on the fly code execution. Python code from your \LaTeX\ file is sent to the background interpreter through a TCP socket. This approach allows your Python code to be executed and the output to be integrated in your \LaTeX\ file in a single compilation run. No additional processing steps are needed. No intermediate files have to be written. No placeholders have to be inserted.
